## 3 Palladium and platinum

### 3.1 Introduction

Palladium and platinum are the longest known and most studied of the six platinum metals [1-11], a reflection of their abundance and consequent availability. Platinum occurs naturally as the element, generally with small amounts of the other platinum metals. It was used as a silver substitute by Colombian Indians and first observed there by Ulloa (1736), who called it platina del Pinto ('little silver of the Pinto river') but the first sample was actually brought to Europe in 1741 by Charles Wood, Assay Master of Jamaica. Palladium was isolated in 1803 by W.H. Wollaston, who was studying the aqua regia-soluble portion of platinum ores (he announced his discovery by an anonymous leaflet advertising its sale through a shop in Soho) and named it after the newly discovered asteroid Pallas [12].

These two metals resemble each other more closely than any of the other 'pairs' in this book. Their chemistry is largely that of the +2 and +4 oxidation states, though there are a few, formally, +1 and +3 compounds and there is an important group of zero valent tertiary phosphine complexes though no stable carbonyl comparable to $\mathrm{Ni}(\mathrm{CO})_{4}$. Unlike nickel(II), where there are large numbers of tetrahedral complexes, these metals adopt almost exclusively square planar geometries in this oxidation state. As expected, they form more compounds in high oxidation states than nickel, partly a consequence of the lower ionization energies (Table 3.1).

Significant differences include:

1. The +4 oxidation state is more stable for platinum.
2. Platinum complexes are usually less labile.
3. There are many more examples of cis- and trans-isomers for platinum (a consequence of (2)).
Platinum in particular forms numbers of stable $\sigma$-bonded alkyls and aryls in both the +2 and +4 states.

### 3.2 The elements and uses

Both palladium and platinum are shiny, silvery metals (with ccp structures), easily drawn and worked when pure. Palladium has the lower melting and boiling points ( 1552 and $3141^{\circ} \mathrm{C}$, respectively); the corresponding figures

Table 3.1 Ionization energies ( $\mathrm{kJ} \mathrm{mol}^{-1}$ )

|  | Ni | Pd | Pt |
| :--- | :---: | :---: | :---: |
| $I_{1}$ | 736.7 | 805 | 870 |
| $I_{2}$ | 1753 | 1875 | 1791 |
| $I_{3}$ | 3393 | 3174 | $(2800)$ |
| $I_{4}$ | 5300 | $(4100)$ | $(3900)$ |

Values in parentheses are estimated.
for platinum are 1772 and $3825^{\circ} \mathrm{C}$. Palladium is the more reactive, attacked by air at $700^{\circ} \mathrm{C}$ and by moist halogens at $20^{\circ} \mathrm{C}$; it dissolves in hot oxidizing mineral acids whereas platinum is only dissolved by aqua regia. Both are attacked by molten caustic alkali.

## Uses

The main uses of palladium [13] are in the electronics and electrical industries, in circuitry and in dental alloys. It finds many catalytic applications in industry, as well as in diffusion cells for the synthesis of hydrogen, and in automobile catalysts. Jewellery and 'three way' auto-catalysts are the principal uses of platinum, which fulfils a wide range of roles in the chemical industry.

The 'three way' catalysts are a major present day use for platinum and rhodium, and a lesser one for palladium; their role in minimizing exhaust emissions (while maximizing energy release) from petrol engines entails complete combustion of hydrocarbons, conversion of CO into $\mathrm{CO}_{2}$ and also removal of nitrogen oxides as $\mathrm{N}_{2}$ (reduction of $\mathrm{NO}_{x}$ ). Platinum metal catalysts are thermally stable and operate at relatively low temperatures. They are prepared by dispersing a mixture of these three metals and alumina, together with certain additives like ceria, over a ceramic or metal matrix to obtain a large surface area. Platinum is the best alkane (and CO ) oxidation catalyst while palladium is superior for alkenes. The role of the $\mathrm{CeO}_{2}$ lies partly in the ability of cerium to switch oxidation states and thus act as a local oxygen store.

Fuel cells essentially reverse the electrolytic process. Two separated platinum electrodes immersed in an electrolyte generate a voltage when hydrogen is passed over one and oxygen over the other (forming $\mathrm{H}_{3} \mathrm{O}^{+}$ and $\mathrm{OH}^{-}$, respectively). Ruthenium complexes are used as catalysts for the electrolytic breakdown of water using solar energy (section 1.8.1).

### 3.2.1 Extraction

The principal countries where platinum and palladium are extracted (along with nickel) are South Africa, Canada and the former USSR, though significant amounts come from Colombia, China and Western Australia [14]. The
ores include all six platinum metals, with palladium and platinum most abundant; relative amounts vary, with the Merensky reef (South Africa) richer in platinum, roughly equal amounts in Sudbury (Ontario), and the Noril'sk deposits (Siberia) richer in palladium. They tend to occur along with nickel and copper ores, e.g. cooperite (PtS), braggite (MS) and sperrylite ( $\mathrm{PtAs}_{2}$ ).

The metals are obtained from the metallic phase of the sulphide matte or the anode slime from electrolytic refining of nickel. In the traditional process for the platinum metals, their separation was facilitated by their solubility in aqua regia and convertibility into $\mathrm{PdCl}_{4}^{2-}$ or $\mathrm{PtCl}_{6}^{2-}$ salts. Nowadays, substantial amounts are obtained using solvent extraction.

### 3.3 Halides

As expected, the heavier metal favours higher oxidation states (Table 3.2): the $\mathbf{M X}_{3}$ compounds are not genuine $\mathbf{M}^{3+}$ species but are diamagnetic, with equal amounts of $\mathrm{M}^{2+}$ and $\mathrm{M}^{4+} . \mathrm{PtF}_{5}$, however, is a platinum( V ) compound.

### 3.3.1 Palladium halides

Syntheses of palladium halides often involve direct reaction with a halogen:

$$
\begin{aligned}
& \mathrm{Pd} \xrightarrow[500^{\circ} \mathrm{C} \text { reflux }]{\mathrm{F}_{2}} \mathrm{PdF}_{3} \xrightarrow{\mathrm{SeF}_{4}{\text { or } \mathrm{SF}_{4}}_{\longrightarrow}} \mathrm{PdF}_{2} \\
& \mathrm{Pd} \xrightarrow[>260^{\circ} \mathrm{C}]{\mathrm{Cl}_{2}} \mathrm{PdCl}_{2} \\
& \mathrm{Pd} \xrightarrow{\mathrm{HBr} / \mathrm{Br}_{2}} \mathrm{PdBr}_{2} \\
& \mathrm{PdCl}_{2} \xrightarrow[\text { sealed tube } 140^{\circ} \mathrm{C}]{5 \% \mathrm{HI}} \mathrm{PdI}_{2} \\
& \mathrm{PdF}_{3} \xrightarrow[\mathrm{~F}_{2}]{300^{\circ} \mathrm{C}} \mathrm{PdF}_{4} \\
& \mathrm{Pd} \xrightarrow[900-1700 \mathrm{~Pa}]{\text { atomic } \mathrm{F}} \mathrm{PdF}_{6}
\end{aligned}
$$

$\mathrm{PdF}_{2}$ is that rare substance, a paramagnetic palladium compound, explicable in terms of (distorted) octahedral coordination of palladium with octahedra sharing corners [15]. It exists in two forms, both having $\mu_{\text {eff }} \sim 2.0 \mu_{\mathrm{B}}$, rather below the spin only value for two unpaired electrons. Bond lengths are $\mathrm{Pd}-\mathrm{F}$ $2.172 \AA$ (two) and $2.143 \AA$ (four) in the tetragonal form (rutile structure).

The other palladium(II) halides are all diamagnetic. $\mathrm{PdCl}_{2}$ exists in well defined $\alpha$ - and $\beta$-forms [16] (as well as a $\gamma$-form); the former has a $\mathrm{PdCl}_{4 / 2}$

Table 3.2 Characteristics of palladium and platinum halides

|  | Palladium |  |  |  | Platinum |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | F | Cl | Br | I | F | Cl | Br | I |
| M ${ }_{2}$ | Pale violet solid | Red solid, dec. $>600^{\circ} \mathrm{C}$ | Brown solid | $\begin{aligned} & \text { Black }(\alpha) \text {, deep } \\ & \text { red }(\beta) \text {, black } \\ & (\gamma), \text { dec. } \\ & >350^{\circ} \mathrm{C} \end{aligned}$ |  | Black-brown solid | Brown solid | Black solid, dec. $>500^{\circ} \mathrm{C}$ |
| MX ${ }_{3}$ | Black solid |  |  |  |  | Green-black solid | Black-green crystal | Black solid |
| MX ${ }_{4}$ | Brick red solid, rapid dec. $>350^{\circ} \mathrm{C}$ |  |  |  | Yellow-brown solid | Red-brown crystal, dec. $>350^{\circ} \mathrm{C}$ | Dark red solid, dec. $>180^{\circ} \mathrm{C}$ | Black crystal, slow dec. RT |
| MX ${ }_{5}$ |  |  |  |  | $\begin{aligned} & \text { Red solid, m.p. } \\ & 80^{\circ} \mathrm{C} \end{aligned}$ |  |  |  |
| MX ${ }_{6}$ | Dark red solid, dec. $\sim 0^{\circ} \mathrm{C}$ |  |  |  | Dark red solid, m.p. $61.3^{\circ} \mathrm{C}$ |  |  |  |

M , palladium or platinum; X , halide.

Figure 3.1 The chain structure of $\alpha-\mathrm{PdCl}_{2}$.
chain structure (Figure 3.1) while the $\beta$-form, synthesized by subliming the $\alpha$ form at $430-460^{\circ} \mathrm{C}$ ) is $\mathrm{Pd}_{6} \mathrm{Cl}_{12}$, similar to the platinum analogue.
$\mathrm{PdBr}_{2}$ also has a chain structure, but puckered, unlike $\alpha-\mathrm{PdCl}_{2}$, with planar coordination (somewhat irregular: $\operatorname{Pd}-\mathrm{Br} 2.34,2.57 \AA$ ). $\mathrm{PdI}_{2}$ has three modifications, all made starting from the black $\gamma$-form precipitated from aqueous $\mathrm{PdCl}_{2}$ reacting with HI at $140^{\circ} \mathrm{C}$; it is traditionally used, because of its insolubility, in the gravimetric determination of palladium. The $\alpha$-form of $\mathrm{PdI}_{2}$ has a structure with tetragonal $\mathrm{PdI}_{4}$ units forming side-by-side chains ( $\mathrm{Pd}-\mathrm{I} 2.60 \AA$ ) while in the $\beta$-form there are planar $\mathrm{Pd}_{2} \mathrm{I}_{6}$ units ( $\mathrm{Pd}-\mathrm{I} 2.61-2.62 \AA$ ) cross-linked with two distant iodines (3.29, $3.49 \AA$ ) to give distorted 6 -coordination.
$\mathrm{PdF}_{3}$ is really $\mathrm{Pd}^{2+} \mathrm{PdF}_{6}^{2-}$; both palladiums have an octahedral environment $\left(\mathrm{Pd}^{2+}-\mathrm{F} 2.17 \AA ; \mathrm{Pd}^{4+}-\mathrm{F} 1.90 \AA\right.$ ); like $\mathrm{PdF}_{2}$, it is paramagnetic with a magnetic moment of $1.75 \mu_{\mathrm{B}}$ per palladium. It is possible that application of pressure causes the $\mathrm{Pd}-\mathrm{F}$ bonds to even out, so that at high pressures the compound could become $\mathrm{PdF}_{3}$ (genuine alkali metal salts of $\mathrm{PdF}_{6}^{3-}$ do exist) [17].
$\mathrm{PdF}_{4}$ is the only stable palladium(IV) halide [18] (testimony to the oxidizing nature of palladium(IV)) and is a very moisture-sensitive diamagnetic red solid; the structure is based on $\mathrm{Pd}_{6} \mathrm{~F}_{24}$ hexameric units linked threedimensionally. It has octahedrally coordinated palladium with two terminal (cis) fluorines and four bridging ones. Despite the absence of other tetrahalides, the complete series of $\mathrm{PdX}_{6}^{2-}$ exist (cf. Ir).
$\mathrm{PdF}_{6}$ has been reported [19] (but not confirmed) to result from the reaction of powdered palladium with atomic fluorine under pressure ( $900-1700 \mathrm{~Pa}$ ) as a dark red solid, unstable at $0^{\circ} \mathrm{C}$ that oxidizes both oxygen and water. An IR band at $711 \mathrm{~cm}^{-1}$ has been assigned as $\nu(\mathrm{Pd}-\mathrm{F})$. There are unsubstantiated claims for $\mathrm{PdF}_{5}$.

### 3.3.2 Platinum halides

Syntheses of platinum halides [20] include

$$
\begin{gathered}
\mathrm{Pt} \xrightarrow[500^{\circ} \mathrm{C}]{\mathrm{Cl}_{2}} \mathrm{PtCl}_{2} \\
\mathrm{Pt} \xrightarrow{\mathrm{Br}_{2}} \mathrm{PtBr}_{3}+\mathrm{PtBr}_{4} \xrightarrow{250^{\circ} \mathrm{C}} \mathrm{PtBr}_{2} \\
\mathrm{H}_{2} \mathrm{PtBr}_{6} \cdot x \mathrm{H}_{2} \mathrm{O} \xrightarrow[180-280^{\circ} \mathrm{C}]{\text { heat }} \mathrm{PtBr}_{2}
\end{gathered}
$$

$$
\begin{aligned}
& \mathrm{Pt} \xrightarrow[525^{\circ} \mathrm{C} \text {, in vacuo }]{\mathrm{I}_{2}} \alpha-\operatorname{PtI}_{2} \\
& \mathrm{~K}_{2} \mathrm{PtI}_{6} \xrightarrow[\text { sealed ampoule }]{240^{\circ} \mathrm{C}} \beta-\mathrm{PtI}_{2} \\
& \mathrm{Pt} \xrightarrow[400-600^{\circ} \mathrm{C}]{\mathrm{Cl}_{2} \text { sealed tube }} \mathrm{PtCl}_{3} \\
& \mathrm{PrBr}_{2} \xrightarrow[125^{\circ} \mathrm{C}]{\mathrm{Br}_{2}, 3 \mathrm{~atm}} \mathrm{PtBr}_{3} \\
& \mathrm{Pt} \xrightarrow[\text { sealed tube }, 160^{\circ} \mathrm{C}]{\mathrm{KI} / \mathrm{L}_{2} / \mathrm{H}_{2} \mathrm{O}} \mathrm{PtI}_{3} \\
& \mathrm{Pt} \xrightarrow[140^{\circ} \mathrm{C}]{\text { exc. } \mathrm{KI} / \mathrm{I}_{2} / \mathrm{H}_{2} \mathrm{O}} \alpha-\mathrm{PtI}_{4} \\
& \mathrm{Pt} \xrightarrow[\text { sealed tube, } 350^{\circ} \mathrm{C}]{\mathrm{SO}_{2} \mathrm{Cl}_{2}} \mathrm{PtCl}_{4} \\
& \mathrm{PtCl}_{2} \xrightarrow[<200^{\circ} \mathrm{C}]{\mathrm{F}_{2}} \mathrm{PtF}_{4} \\
& \mathrm{Pt} \xrightarrow[150^{\circ} \mathrm{C}]{\mathrm{Br}_{2}} \mathrm{PtBr}_{4} \\
& \mathrm{PtCl}_{2} \xrightarrow[350^{\circ} \mathrm{C}]{\mathrm{F}_{2}} \mathrm{PtF}_{5} \\
& \mathrm{Pt} \text { (hot wire) } \xrightarrow[\text { 2. condense }]{\text { 1. } \mathrm{F}_{2}} \mathrm{PtF}_{6}
\end{aligned}
$$

$\mathrm{PtF}_{2}$ is unknown, presumably unstable with respect to the disproportionation

$$
2 \mathrm{PtF}_{2} \rightarrow \mathrm{Pt}+\mathrm{PtF}_{4}
$$

This would occur as a consequence of the stability of the low spin $d^{6}$ platinum(IV) state and of the oxidizing power of fluorine. $\mathrm{PtCl}_{2}$, like the other platinum dihalides, is insoluble in water. It has two crystalline forms: the $\beta$-form is similar to $\beta$ - $\mathrm{PdCl}_{2}$ (Figure 3.2; $\mathrm{Pt}-\mathrm{Cl} 2.34-2.39 \AA, \mathrm{Pt}-\mathrm{Pt} 3.32-$ $3.40 \AA$ ). This transforms to the $\alpha$-form at $500^{\circ} \mathrm{C}$; this form has square planar coordination of platinum ( $\mathrm{Pt}-\mathrm{Cl} 2.299-2.310 \AA$ ) in a chain structure [21]. $\mathrm{PtBr}_{2}$ is isomorphous with $\beta-\mathrm{PtCl}_{2}$, and thus believed to be $\mathrm{Pt}_{6} \mathrm{Br}_{12}$, while $\beta-\mathrm{PtI}_{2}$ is isomorphous with $\beta-\mathrm{PdI}_{2}$ [20].

All the trihalides are mixed valence compounds. $\mathrm{PtF}_{3}$ is isostructural with $\mathrm{PdF}_{3} \cdot \mathrm{PtX}_{3}(\mathrm{X}=\mathrm{Cl}, \mathrm{Br}, \mathrm{I})$ cannot be made by straightforward thermal decomposition of $\mathrm{PtX}_{4}$ [22] under open conditions but by routes involving continuous decomposition and formation under closed, equilibrium conditions.

Figure 3.2 The structure of $\beta-\mathrm{PtCl}_{2}\left(\mathrm{Pt}_{6} \mathrm{Cl}_{12}\right)$. (Reproduced with permission from S.A. Cotton and F.A. Hart, The Heavy Transition Elements, Macmillan Press Ltd, 1975, p. 109.)
$\mathrm{PtCl}_{3}$ and $\mathrm{PtBr}_{3}$ (Figure 3.3) are isomorphous and contain both $\mathrm{Pt}_{6} \mathrm{X}_{12}$ clusters and $\left[\mathrm{PtX}_{2} \mathrm{X}_{4 / 2}\right]_{\infty}$ chains, thus representing a 'half way' stage in decomposing $\mathrm{PtX}_{4}$ [20].
$\mathrm{PtF}_{4}$ prepared by various routes, including fluorination $\left(\mathrm{BrF}_{3}\right)$ of $\mathrm{PtCl}_{4}$ or heating $\mathrm{PtF}_{6}$, is isostructural with $\mathrm{PdF}_{4}$ ( $\mathrm{Pt}-\mathrm{F}$ (terminal) $1.818 \AA, \mathrm{Pt}-\mathrm{F}$ (bridge) $2.048 \AA$ ) [23]. The other tetrahalides similarly have chain structures (Figure 3.4) with two cis-terminal halides.

Figure 3.3 The structure of $\mathrm{PtBr}_{3}$, showing the $\mathrm{Pt}_{6} \mathrm{Br}_{12}$ and ${ }_{\infty}^{1}\left[\mathrm{PtBr}_{2} \mathrm{Br}_{4 / 2}\right]$ structural units. (Reproduced with permission from Transit. Met. Chem., 1975/6, 1, 45.)

Figure 3.4 The chain structure adopted by $\mathrm{PtX}_{4}$ in the solid state.
The iodide is polymorphic, with the $\alpha$ - and $\gamma$-forms known to have this structure (bond lengths are $2.65-2.72 \AA\left(\gamma-\mathrm{PtI}_{4}\right), 2.62-2.78 \AA\left(\alpha-\mathrm{PtI}_{4}\right)$ 2.41-2.54 $\AA\left(\mathrm{PtBr}_{4}\right)$.

On heating, $\mathrm{PtCl}_{4}$ and $\mathrm{PtBr}_{4}$ give $\mathrm{PtX}_{2}$ but $\mathrm{PtI}_{4}$ first yields $\mathrm{PtI}_{3}$ or $\mathrm{Pt}_{3} \mathrm{I}_{8}$, depending on conditions [24].

Evaporation of solutions of platinum in aqua regia gives yellow crystals of the hydrates trans- $\left[\mathrm{PtCl}_{4}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right] \cdot 3 \mathrm{H}_{2} \mathrm{O}$ and $f a c-\left[\mathrm{PtCl}_{3}\left(\mathrm{H}_{2} \mathrm{O}\right)_{3}\right] \mathrm{Cl} \cdot \frac{1}{2} \mathrm{H}_{2} \mathrm{O}[25]$.
$\mathrm{PtF}_{5}$, made by fluorination of $\mathrm{PtCl}_{2}$ at $350^{\circ} \mathrm{C}$ disproportionates above its m.p.

$$
2 \mathrm{PtF}_{5} \rightarrow \mathrm{PtF}_{4}+\mathrm{PtF}_{6}
$$

Its structure is not known but it may be a tetramer, like $\mathrm{RhF}_{5}$.
The original synthesis of $\mathrm{PtF}_{6}$ [26] involves electrical ignition of a platinum wire in a fluorine atmosphere then rapidly cooling the vapour (liquid nitrogen); it is also reported to result from the reaction of the elements under pressure at $200^{\circ} \mathrm{C}$. It has a molecular structure ( $\mathrm{Pt}-\mathrm{F} 1.839 \AA$ ) and is intensely reactive, forming $\mathrm{PtF}_{5}$ and $\mathrm{PtF}_{4}$ on heating, vigorously decomposing water to $\mathrm{O}_{2}$, and even attacking dry glass. It also is readily reduced:

$$
\mathrm{O}_{2}+\mathrm{PtF}_{6} \rightarrow \mathrm{O}_{2}^{+} \mathrm{PtF}_{6}^{-}
$$

### 3.3.3 Halide complexes

An extensive range of mono- and binuclear halide complexes of platinum and palladium exist. Of the tetrahalometallate(II) ions, some like $\mathrm{PtF}_{4}^{2-}$ and $\mathrm{PdI}_{4}^{2-}$ are elusive, the latter only having been characterized in solution.

$$
\begin{aligned}
& \mathrm{PdCl}_{2}\left.\xrightarrow[\mathrm{HCl}]{\mathrm{MCl}} \mathrm{M}_{2} \mathrm{PdCl}_{4} \text { (red-brown) (M, e.g. } \mathrm{K}, \mathrm{NH}_{4}\right)(\mathrm{Pt} \text { similarly) } \\
& \mathrm{K}_{2} \mathrm{PdCl}_{4} \xrightarrow{\mathrm{Br}^{-}} \mathrm{K}_{2} \mathrm{PdBr}_{4} \text { (dark red) } \\
& \mathrm{K}_{2} \mathrm{PtCl}_{4} \xrightarrow{\mathrm{NaBr} / \mathrm{HBr}} \mathrm{~K}_{2} \mathrm{PtBr}_{4} \text { (brown) } \\
& \mathrm{K}_{2} \mathrm{PtCl}_{4} \xrightarrow[\mathrm{exI} .]{\text { ext }} \mathrm{K}_{2} \mathrm{PtI}_{4} \text { (black) }
\end{aligned}
$$

Table 3.3 Bond lengths in $\mathrm{MX}_{4}^{2-}$ together with $\mathrm{M}-\mathrm{X}$ stretching frequencies $\left(\mathrm{cm}^{-1}\right.$ )

| Ion | Cation | $\mathrm{M}-\mathrm{X}(\AA)$ | Ion | $\nu_{1}\left(\mathbf{A}_{1 \mathrm{~g}}\right)$ | $\nu_{2}\left(\mathbf{B}_{\mathrm{lg}}\right)$ | $\nu_{6}\left(\mathrm{E}_{\mathrm{u}}\right)$ |
| :--- | :--- | :---: | :--- | :---: | :---: | :---: |
| $\mathrm{PdCl}_{4}^{2-}$ | $\mathrm{NH}_{4}^{+}$ | 2.299 | K | 310 | 275 | 336 |
| $\mathrm{PtCl}_{4}^{2-}$ | $\mathrm{K}^{+}$ | 2.308 | $\mathrm{Bu}_{4} \mathbf{N}$ | 330 | 312 | 317 |
| $\mathrm{PdBr}_{4}^{2-}$ | $\mathrm{K}^{+}$ | 2.438 | (aq.) | 188 | 172 | 225 |
| $\mathrm{PtBr}_{4}^{2-}$ | $\mathrm{K}^{+}$ | 2.445 | - | 208 | 194 | 243 |
| $\mathrm{PtI}_{4}^{-}$ | $\left(\mathrm{in}\left(\mathrm{MeNH}_{3}\right)_{4}\right.$ | 2.625 | (aq.) | 155 | 142 | - |
|  | $\left.\mathrm{Pt}_{3} \mathrm{I}_{11}\right)$ |  |  |  |  |  |

They have square planar structures; corresponding bond lengths and vibrational frequencies are given in Table 3.3.
$\mathrm{PtI}_{4}^{2-}$ has been identified in the unusual $\left(\mathrm{MeNH}_{3}\right)_{4} \mathrm{Pt}_{3} \mathrm{I}_{11}$, a mixed-valence compound with $\mathrm{PtI}_{4}^{2-}, \mathrm{PtI}_{6}^{2-}$ and $\mathrm{Pt}_{2} \mathrm{I}_{6}^{2-}$ ions all present $\left(\mathrm{K}_{2} \mathrm{PtI}_{4}\right.$ has not definitely been confirmed) [27].

Genuine palladium(III) fluoroferrates have been made [28]

$$
\mathrm{PdF}_{3}+2 \mathrm{AF}+\mathrm{BF} \underset{3 \mathrm{kbar}}{400^{\circ} \mathrm{C}} \mathrm{~A}_{2} \mathrm{BPdF}_{6}
$$

( $\mathrm{A}=\mathrm{K}, \mathrm{Rb}, \mathrm{Cs} ; \mathrm{B}=\mathrm{Li}, \mathrm{Na}, \mathrm{K}$ ).
The beige to green solids have the elpasolite structure. Magnetic measurements confirm the $\mathfrak{t}_{2 \mathrm{~g}}^{6} \mathrm{e}_{\mathrm{g}}^{1}$ configuration; they give strong ESR signals $\left(\mathrm{Na}_{3} \mathrm{PdF}_{6} \mathrm{~g}_{\perp}=2.312, \mathrm{~g}_{\|}=2.025\right)$ and exhibit a peak in the photoelectron spectra intermediate between those for palladium(II) and palladium(IV). $\mathrm{K}_{2} \mathrm{NaPdF}_{6}$ has been shown (X-ray) to have Jahn-Teller-distorted $\mathrm{PdF}_{6}^{3-}$ octahedra with $\mathrm{Pd}-\mathrm{F}=1.95 \AA$ (four) and $2.14 \AA$ (two).
'Chloroplatinic acid', $\left(\mathrm{H}_{3} \mathrm{O}\right)_{2} \mathrm{PtCl}_{6} \cdot x \mathrm{H}_{2} \mathrm{O}(x \sim 2)$, is obtained as brownred crystals by dissolving platinum in aqua regia, followed by one or two evaporations with hydrochloric acid; it is a very useful starting material. Thermogravimetric data show that, after initial dehydration (up to $125^{\circ} \mathrm{C}$ ), $\mathrm{PtCl}_{4}$ is formed at $220^{\circ} \mathrm{C}$ and $\beta-\mathrm{PtCl}_{2}$ at $350^{\circ} \mathrm{C}$, before final decomposition to platinum around $500^{\circ} \mathrm{C}$ [29]. The $\mathrm{Pt}-\mathrm{Cl}$ bond length is $2.323 \AA$ in $\left(\mathrm{H}_{3} \mathrm{O}\right)_{2} \mathrm{PtCl}_{6}$ [30].

All eight possible octahedral $\mathrm{MX}_{6}^{2-}(\mathrm{X}=\mathrm{F}, \mathrm{Cl}, \mathrm{Br}, \mathrm{I})$ have been made [31]:

$$
\begin{aligned}
& \mathrm{A}_{2} \mathrm{PdCl}_{6} \begin{array}{c}
200-300^{\circ} \mathrm{C} \\
\mathrm{~F}_{2} \\
\mathrm{~A}_{2} \\
\mathrm{PdF}_{6}
\end{array} \quad(\mathrm{~A}=\mathrm{K} \text { to } \mathrm{Cs}) \\
& \mathrm{M} \xrightarrow[2 . \mathrm{ACl}]{\text { 1.aqua regia }} \mathrm{A}_{2} \mathrm{MCl}_{6} \quad(\mathbf{M}=\mathrm{Pd}, \mathrm{Pt}) \\
& \mathrm{K}_{2} \mathrm{PtCl}_{6} \xrightarrow{\mathrm{KHF}_{2} \text { melt }} \mathrm{K}_{2} \mathrm{PtF}_{6} \\
& \mathrm{~A}_{2} \mathrm{PdBr}_{4} \xrightarrow{\mathrm{Br}_{2}} \mathrm{M}_{2} \mathrm{PdBr}_{6} \\
& \mathrm{PdCl}_{6}^{2-} \xrightarrow[\mathrm{CsI}]{\text { exc. }} \mathrm{Cs}_{2} \mathrm{PdI}_{6}
\end{aligned}
$$

Table 3.4 Bond lengths in $\mathrm{MX}_{6}^{2-}(\AA)$

| Pd complexes | Counter-ion | $\mathrm{M}-\mathrm{X}$ | Pt complexes | Counter-ion | $\mathrm{M}-\mathrm{X}$ |
| :--- | :--- | :--- | :--- | :--- | :---: |
| $\mathrm{PdF}_{6}^{2-}$ | $\mathrm{XeFF}_{5}^{+}$ | 1.893 | $\mathrm{PtF}_{6}^{2-}$ | $\mathrm{NH}_{4}^{+}$ | 1.942 |
|  | $\mathrm{~K}^{+}$ | 1.896 |  | $\mathrm{~K}^{+}$ | 1.922 |
| $\mathrm{PdCl}_{6}^{2-}$ | $\mathrm{NH}_{4}^{+}$ | 2.300 | $\mathrm{PtCl}_{6}^{2-}$ | $\mathrm{K}^{+}$ | $2.315-2.316$ |
|  | $\mathrm{~K}^{+}$ | 2.309 |  |  |  |
|  | $\mathrm{Me}_{4} \mathrm{~N}^{+}$ | 2.312 |  |  |  |

|  |  |  | $\mathrm{PtI}_{6}^{2-}$ | $\mathrm{pyH}^{+}$ | $2.661-2.670$ |
|  |  |  |  | $\mathrm{Cs}^{+}$ | 2.673 |

$$
\begin{aligned}
\mathrm{PtCl}_{4} & \xrightarrow{\mathrm{HCl}} \mathrm{H}_{2} \mathrm{PtCl}_{6} \xrightarrow{\mathrm{ACl}} \mathrm{M}_{2} \mathrm{PtCl}_{6} \quad(\mathrm{~A}=\mathrm{K} \text { to } \mathrm{Cs}) \\
\mathrm{Pt} & \xrightarrow[2 . \mathrm{A}^{+}]{\text {1. } \mathrm{HBr} / \mathrm{Br}_{2}} \mathrm{~A}_{2} \mathrm{PtBr}_{6} \\
\mathrm{H}_{2} \mathrm{PtCl}_{6} & \xrightarrow{\text { exc. AI }} \mathrm{A}_{2} \mathrm{PtI}_{6}
\end{aligned}
$$

The palladium compounds are generally, as expected, less stable. Therefore, $\mathrm{PdF}_{6}^{2-}$ is decomposed by water while $\mathrm{PtF}_{6}^{2-}$ can be synthesized in aqueous solution. The $\mathrm{M}_{2} \mathrm{PdCl}_{6}$ salts decompose on heating to $200^{\circ} \mathrm{C}$. Bond lengths for a selection of the $\mathbf{M X}_{6}^{2-}$ ions are given in Table 3.4 and the structure of $\mathrm{K}_{2} \mathrm{PtCl}_{6}$ is shown in Figure 3.5 (based on the fluorite structure with $\mathrm{K}^{+}$in the fluoride positions and $\mathrm{PtCl}_{6}^{2-}$ taking the place of the potassium) [32].

Figure 3.5 The crystal structure of $\mathrm{K}_{2} \mathrm{PtCl}_{6}$. (Reproduced from A.F. Wells, Structural Inorganic Chemistry, 4th edn, 1975, p. 387, by permission of Oxford University Press.)

Synthesis for the octahedral $\mathrm{MF}_{6}^{-}$ions include [33]

$$
\begin{aligned}
\mathrm{PdF}_{4} \xrightarrow[\mathrm{KrF}_{2} / \mathrm{O}_{2} \text { or NaF }]{\mathrm{HF}} \mathrm{X}^{+} \mathrm{PdF}_{6}^{-} \quad\left(\mathrm{X}=\mathrm{O}_{2}, \mathrm{Na}\right) \\
\mathrm{Pd} \xrightarrow[320^{\circ} \mathrm{C}, 60000 \mathrm{psi}]{\mathrm{F}_{2} / \mathrm{O}_{2}} \mathrm{O}_{2}^{+} \mathrm{PdF}_{6}^{-} \\
\mathrm{PtF}_{6} \xrightarrow{\mathrm{O}_{2}} \mathrm{O}_{2}^{+} \mathrm{PtF}_{6}^{-} \xrightarrow[\mathrm{IF}_{5}]{\mathrm{MF}} \mathrm{M}^{+} \mathrm{PtF}_{5}^{-} \quad(\mathrm{M}=\mathrm{K} \text { to } \mathrm{Cs})
\end{aligned}
$$

The magnetic moment for $\mathrm{PtF}_{6}^{-}\left(\mathrm{K}^{+}\right.$salt $)$is $0.87 \mu_{\mathrm{B}}\left(\mathrm{t}_{2 \mathrm{~g}}^{5}\right)$. The bond lengths for this ion are, as expected, intermediate between $\mathrm{PtF}_{6}$ and $\mathrm{PtF}_{6}^{2-}$ (Table 3.5).

Both these ions are strong oxidizing agents; $\mathrm{PtF}_{6}^{-}$will, unlike $\mathrm{PtF}_{6}^{2-}$, oxidize water to $\mathrm{O}_{2}$ and $\mathrm{O}_{3}$. Vibrational data for a number of $\mathrm{MX}_{6}^{n-}$ species are listed in Tables 3.6 and 3.7.

As expected, there is a shift to lower frequency as the oxidation state of the metal decreases and as the mass of the halogen increases.

Mixed haloplatinate(IV) ions have been synthesized [34] by use of substitution reactions on $\mathrm{PtCl}_{6}^{2-}$ and $\mathrm{PtBr}_{6}^{2-}$; using the stronger trans-influence of Br , the cis-isomers can be made by treating $\mathrm{PtBr}_{6}^{2-}$ with $\mathrm{Cl}^{-}$(in the presence of $\mathrm{Br}_{2}$ ):

$$
\begin{aligned}
\mathrm{PtBr}_{6}^{2-} & \xrightarrow{\mathrm{Cl}^{-}} \mathrm{PtBr}_{5} \mathrm{Cl}^{2-} \rightarrow \text { cis- } \mathrm{PtBr}_{4} \mathrm{Cl}_{2}^{2-} \rightarrow \text { fac- } \mathrm{PtBr}_{3} \mathrm{Cl}_{3}^{2-} \\
& \rightarrow \text { cis }-\mathrm{PtBr}_{2} \mathrm{Cl}_{4}^{2-} \rightarrow \mathrm{PtBrCl}_{5}^{2-} \rightarrow \mathrm{PtCl}_{6}^{2-}
\end{aligned}
$$

The trans-isomers can be made by substitution of $\mathrm{Br}^{-}$

$$
\mathrm{PtBrCl}_{5}^{2-} \xrightarrow{\mathrm{Br}^{-}} \text {trans }-\mathrm{PtBr}_{2} \mathrm{Cl}_{4}^{2-} \rightarrow \text { mer }-\mathrm{PtBr}_{3} \mathrm{Cl}_{3}^{2-} \quad \text { etc. }
$$

Reaction mixtures can be separated by chromatography. Individual isomers can be identified by their vibrational spectra.

In the case of $\mathrm{PtF}_{n} \mathrm{Cl}_{6-n}^{2-}$, it has even been possible to synthesize isotopically labelled species using isotopically labelled HCl (Figure 3.6).

Spectra of trans $-\mathrm{Pt}^{35} \mathrm{Cl}_{2} \mathrm{~F}_{4}^{2-}$ and the cis-isomer show the simpler spectra expected from the trans-isomer (three $\mathrm{Pt}-\mathrm{F}$ and two $\mathrm{Pt}-\mathrm{Cl}$ stretches) compared with the cis-isomer (four $\mathrm{Pt}-\mathrm{F}$ and two $\mathrm{Pt}-\mathrm{Cl}$ stretches). The complexity of the spectrum of the cis-isomer is also the result of the lack of a centre of symmetry in the cis-form; the selection rules allow all bands to be seen in both the IR and the Raman spectra (in theory, at least).

Figure 3.6 IR (upper) and Raman (lower) spectra of $\mathrm{Cs}_{2}\left[\mathrm{Pt}^{35} \mathrm{Cl}_{2} \mathrm{~F}_{4}\right]$ : cis-isomer on the left; transisomer on the right. (Reproduced with permission from Z. Naturforsch., Teil B, 1989, 44, 619.)

Figure 3.7 The dimeric structure of $\left[\mathrm{Pt}_{2} \mathrm{Cl}_{6}\right]^{2-}$.

The structures of $f a c$ - $\left(\mathrm{py}_{2} \mathrm{CH}_{2}\right)\left[\mathrm{PtF}_{3} \mathrm{Cl}_{3}\right]$ and mer- $\left(\mathrm{py}_{2} \mathrm{CH}_{2}\right)\left[\mathrm{PtF}_{3} \mathrm{Cl}_{3}\right]$ show the greater trans-influence of chloride. The $\mathrm{Pt}-\mathrm{F}$ bonds are $1.950-1.995 \AA$ in the fac-isomer and 1.936-1.937 (trans to F) and $1.972 \AA$ (trans to Cl ) in the mer-isomer; similarly $\mathrm{Pt}-\mathrm{Cl}$ is $2.265-2.285 \AA$ in the fac-isomer and 2.271 (trans to F ) and 2.292-2.303 $\AA$ (trans to Cl ) in the mer-isomer [35].
The $\mathrm{M}_{2} \mathrm{X}_{6}^{2-}$ salts are the simplest binuclear complexes [36]

$$
\begin{aligned}
& \mathrm{MCl}_{4}^{2-} \xrightarrow[\mathrm{H}_{2} \mathrm{O}]{\mathrm{Ph}_{3} \mathrm{MeAsCl}^{2}}\left(\mathrm{Ph}_{3} \mathrm{MeAs}\right)_{2} \mathrm{M}_{2} \mathrm{Cl}_{6} \quad(\mathrm{M}=\mathrm{Pd}, \mathrm{Pt}) \\
& \mathrm{MCl}_{4}^{2-} \xrightarrow[\mathrm{H}_{2} \mathrm{O}]{\mathrm{cyclo-C}_{3} \mathrm{H}_{3} \mathrm{C}_{3}^{+} \mathrm{Cl}^{-}}\left(\text {cyclo-C } \mathrm{C}_{3} \mathrm{H}_{7} \mathrm{C}_{3}\right)_{2} \mathrm{M}_{2} \mathrm{Cl}_{6} \\
& \mathrm{MBr}_{2} \xrightarrow[\mathrm{H}_{2} \mathrm{O}]{\mathrm{Et}_{4} \mathrm{NBr}^{2}}\left(\mathrm{Et}_{4} \mathrm{~N}\right)_{2} \mathrm{M}_{2} \mathrm{Br}_{6} \\
& \mathrm{MI}_{2} \xrightarrow[\mathrm{Et}_{4} \mathrm{NI}]{\text { e.g. } \mathrm{EtOH}}\left(\mathrm{Et}_{4} \mathrm{~N}\right)_{2} \mathrm{M}_{2} \mathrm{I}_{6}
\end{aligned}
$$

They have di- $\mu$-halogen bridged structures and are planar (Figure 3.7).
Typical bond lengths in $\mathrm{Pd}_{2} \mathrm{Cl}_{6}^{2-}$ are $\mathrm{Pd}-\mathrm{Cl} 2.27 \AA$ (terminal) and $2.32 \AA$ (bridge) with $\mathrm{Pd}-\mathrm{Pd} 3.41 \AA$ and in $\mathrm{Pd}_{2} \mathrm{Br}_{6}^{2-} \mathrm{Pd}-\mathrm{Br} 2.398-2.405 \AA$ (terminal) and $2.445-2.452 \AA$ (bridge).

Dinuclear platinum(IV) complexes have recently been reported:

$$
\mathrm{PtX}_{6}^{2-} \xrightarrow[\text { heat }]{\mathrm{CF}_{3} \mathrm{CO}_{2} \mathrm{H}} \mathrm{Pt}_{2} \mathrm{X}_{10}^{2-} \quad(\mathrm{X}=\mathrm{Cl}, \mathrm{Br})
$$

They have edge-sharing bioctahedral structures [37].

### 3.4 Other binary complexes

Palladium is notable for its ability to absorb (and desorb) hydrogen; diffusion through thin palladium films can be used to separate hydrogen from other gases. At 300 K , the $\mathrm{Pd} / \mathrm{H}$ phase diagram shows an $\alpha$-phase up to $\mathrm{PdH}_{0.03}$, a two-phase region up to $\mathrm{PdH}_{0.56}$ after which the $\beta$-phase becomes the sole species. The greatest $\mathrm{H}: \mathrm{Pd}$ ratio obtainable is $\sim 0.83: 1$ (at 195 K ). The hydride reportedly has a defect NaCl structure.

The ability of palladium and platinum to catalyse hydrogenation reactions is of considerable industrial importance.

Tertiary hydrides can be made [38, 39]

$$
\begin{array}{ll}
\mathrm{AH}+\mathrm{Pd} \text { sponge } \frac{\mathrm{H}_{2}}{20 \mathrm{kbar}, 400^{\circ} \mathrm{C}} \mathrm{~A}_{2} \mathrm{PdH}_{4} & (\mathrm{~A}=\mathrm{Rb}, \mathrm{Cs}) \\
\mathrm{AH}+\mathrm{Pd} \text { sponge } \underset{70 \mathrm{kbar}, 300-350^{\circ} \mathrm{C}}{\mathrm{H}_{2}} \mathrm{~A}_{3} \mathrm{PdH}_{5} & (\mathrm{~A}=\mathrm{K}, \mathrm{Rb}, \mathrm{Cs})
\end{array}
$$

$\mathrm{Na}_{2} \mathrm{PdH}_{4}, \mathrm{~A}_{2} \mathrm{PtH}_{4}(\mathrm{M}=\mathrm{Na}, \mathrm{K})$ and $\mathrm{K}_{2} \mathrm{PtH}_{6}$ are similarly made, only $\mathrm{K}_{2} \mathrm{PtH}_{6}$ requiring any high hydrogen pressure.

All $\mathrm{A}_{2} \mathrm{MH}_{4}$ contain square planar $\mathrm{MH}_{4}^{2-}$ units, but at high temperatures the $\mathrm{A}_{2} \mathrm{MH}_{4}$ salts adopt the $\mathrm{K}_{2} \mathrm{PtCl}_{6}$ structure with hydrogens able to move between different square planar orientations. $\mathbf{M}_{2} \mathbf{P d H}_{2}(\mathbf{M}=\mathrm{Li}, \mathrm{Na})$ compounds have metallic lustre and display metallic conductivity [40].

Palladium and platinum combine on heating with the group V (15) and VI (16) elements [41].

The important oxides are black PdO and brown $\mathrm{PtO}_{2}$. The former can be made by heating palladium in oxygen; other methods include heating $\mathrm{PdCl}_{2}$ in an $\mathrm{NaNO}_{3}$ melt at $520^{\circ} \mathrm{C}$. A hydrated form precipitates from aqueous solution, e.g. when $\mathrm{Pd}\left(\mathrm{NO}_{3}\right)_{2}$ solution is boiled. It has 4 -coordinate square planar palladium (Figure 3.8).

Black $\mathrm{PdO}_{2}$ (rutile structure) is claimed to result from heating PdO with $\mathrm{KClO}_{3}$ under pressure at $950^{\circ} \mathrm{C}$, then rapidly cooling to room temperature. $\mathrm{PtO}_{2}$, however, is well authenticated; it is made in hydrated form by hydrolysis (with $\mathrm{Na}_{2} \mathrm{CO}_{3}$ ) of boiling $\mathrm{PtCl}_{6}^{2-}$ solution. It dehydrates on heating.

PtS (PdO structure) and PdS (similar) are prepared from $\mathrm{M}^{2+}$ (aq.) and $\mathrm{H}_{2} \mathrm{~S}$ or $\mathrm{Li}_{2} \mathrm{~S}$. They have square planar coordination of $\mathrm{M}^{2+}$ (Figure 3.9).

On heating with sulphur, $\mathrm{MS}_{2}$ result. $\mathrm{PtS}_{2}$ has the 6 -coordinate $\mathrm{CdI}_{2}$ structure whereas $\mathrm{PtS}_{2}$ is $\mathrm{Pd}^{2+}\left(\mathrm{S}_{2}^{2-}\right)$ in a distorted pyrite structure (4-coordinate $\operatorname{PdPd}-S 2.30 \AA$ ) confirming the preference for the divalent state for

Figure 3.8 The structure of PdO and PtO. (Reproduced from A.F. Wells, Structural Inorganic Chemistry, 4th edn, 1975, p. 446, by permission of Oxford University Press.)

Figure 3.9 The structure of PtS. (Reproduced from A.F. Wells, Structural Inorganic Chemistry, 4th edn, 1975, p. 661, by permission of Oxford University Press.)
palladium. Other phases like $\mathrm{Pd}_{2.2} \mathrm{~S}, \mathrm{Pd}_{3} \mathrm{~S}$ and $\mathrm{Pd}_{4} \mathrm{~S}$ (the last two both alloy like) exist. The former is a superconductor below 1.63 K .

The tellurides MTe reportedly have the NiAs structure.
The pyrites structure is exhibited by several pnictides: $\mathrm{MAs}_{2}$ and $\mathrm{MSb}_{2}$ ( $\mathrm{M}=\mathrm{Pd}, \mathrm{Pt}$ ) and $\mathrm{PtP}_{2}$ (Figure 3.10).
$\mathrm{PdP}_{2}$, however, contains continuous chains of phosphorus atoms (with, as expected, planar 4-coordinate Pd ) while $\mathrm{PdP}_{3}$ has the $\mathrm{CoAs}_{3}$ structure ( $\mathrm{P}_{4}$ rings).

### 3.5 Aqua ions

Syntheses of palladium and platinum aqua ions [42] include

$$
\begin{array}{r}
\mathrm{PdO} \xrightarrow{\mathrm{HClO}_{4}} \mathrm{Pd}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}^{2+} \\
\mathrm{PtCl}_{4}^{2-} \xrightarrow{\mathrm{AgClO}_{4}} \mathrm{Pt}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}^{2+}
\end{array}
$$

Figure 3.10 The structure of $\mathrm{PtP}_{2}$. (Reproduced with permission from S.A. Cotton and F.A. Hart, The Heavy Transition Elements, Macmillan Press Ltd, 1975, p. 111.)

Hydrated palladium perchlorate has been isolated as brown needles of $\mathrm{Pd}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}\left(\mathrm{ClO}_{4}\right)_{2}$ by first dissolving palladium sponge in concentrated $\mathrm{HNO}_{3}$, adding $72 \% \mathrm{HClO}_{4}$, evaporating until it fumes strongly and then crystallizing. $\mathrm{Pd}\left(\mathrm{NO}_{3}\right)_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}$ is made by the reaction of palladium with nitric acid; it is also brown.

### 3.6 Palladium(0) and platinum(0) compounds

### 3.6.1 Tertiary phosphine complexes

The tertiary phosphine complexes are the most important zerovalent compounds. They are frequently prepared by reductive methods, often using the phosphine as the reducing agent [43], e.g.

$$
\operatorname{Pd}\left(\eta^{5}-\mathrm{C}_{5} \mathrm{H}_{5}\right)\left(\eta^{3}-\mathrm{C}_{3} \mathrm{H}_{5}\right) \xrightarrow{\mathrm{PR}_{3}} \operatorname{Pd}\left(\mathrm{PR}_{3}\right)_{2}
$$

$\left(\mathrm{R}=\mathrm{Bu}^{\mathrm{t}}, \mathrm{cy} ; \mathrm{PR}_{3}=\mathrm{PPhBu}_{2}^{\mathrm{t}}\right)$

$$
\begin{aligned}
\text { trans }-\mathrm{PtCl}_{2}\left(\mathrm{Pcy}_{3}\right)_{2} & \xrightarrow{\mathrm{Na} / \mathrm{Hg}} \operatorname{Pt}\left(\mathrm{Pcy}_{3}\right)_{2} \\
\text { [2-methylallyl } \mathrm{PdCl}]_{2} & \xrightarrow{\text { exc. } \mathrm{PR}_{3}} \operatorname{Pd}\left(\mathrm{PR}_{3}\right)_{n}
\end{aligned}
$$

$\left(\mathrm{PR}_{3}=\mathrm{PMe}_{3}, \mathrm{PMe}_{2} \mathrm{Ph}, \mathrm{PBu}_{3}^{n}(n=4) ; \mathrm{PR}_{3}=\mathrm{Pcy}_{3}, \operatorname{PPr}_{3}^{\mathrm{i}}, \mathrm{Pbz}_{3}(n=3)\right.$; $\left.\mathrm{PR}_{3}=\mathrm{PBu}_{2}^{\mathrm{t}} \mathrm{Ph}(n=2)\right)$

$$
\text { cis }-\mathrm{PtCl}_{2}\left(\mathrm{PPh}_{2} \mathrm{CF}_{3}\right)_{2} \xrightarrow[\mathrm{NaBH}_{4}]{\mathrm{PP}_{2} \mathrm{CF}_{3}} \mathbf{P t}\left(\mathrm{PPh}_{2} \mathrm{CF}_{3}\right)_{3}
$$

Compounds with high coordination numbers sometimes eliminate a molecule of phosphine on heating:

$$
\begin{array}{ll}
\mathrm{M}\left(\mathrm{PR}_{3}\right)_{4} \xrightarrow[\text { in vacuo }]{70^{\circ} \mathrm{C}} \mathrm{M}\left(\mathrm{PR}_{3}\right)_{3} & (\mathrm{M}=\mathrm{Pd}, \mathrm{Pt} ; \mathrm{R}=\mathrm{Bu}, \mathrm{Et}) \\
\mathrm{M}\left(\operatorname{PPr}_{3}^{\mathrm{i}}\right)_{3} \xrightarrow[\text { in vacuo }]{\text { heat }} \mathbf{M}\left(\operatorname{PPr}_{3}^{\mathrm{i}}\right)_{2} & (\mathrm{M}=\mathrm{Pd}, \mathrm{Pt})
\end{array}
$$

Tetrahedral structures have been established for $\operatorname{Pd}\left(\mathrm{PPh}_{3}\right)_{4}$ (rather long $\mathrm{Pd}-\mathbf{P}$ bonds at $2.443 \AA), \operatorname{Pd}\left[\mathrm{P}\left(\mathrm{CH}_{2} \mathrm{OH}\right)_{3}\right]_{4}(\mathrm{Pd}-\mathbf{P} 2.321$ to $2.326 \AA)$, $\mathrm{Pt}\left(\mathrm{PF}_{3}\right)_{4}$ (electron diffraction: $\left.\mathrm{Pt}-\mathrm{P} 2.229 \AA\right), \mathrm{Pd}\left[\mathrm{P}(\mathrm{C} \equiv \mathrm{CPh})_{3}\right]_{4}, \mathrm{Pt}\left(\mathrm{PEt}_{3}\right)_{4}$ and $\mathrm{Pt}\left(\mathrm{PMe}_{2} \mathrm{Ph}\right)_{4}$ [44]. Trigonal planar structures are found for $\mathrm{Pt}\left(\mathrm{Pcy}_{3}\right)_{3}$, $\operatorname{Pd}\left(\mathrm{PPh}_{3}\right)_{3}(\mathrm{Pd}-\mathrm{P} 2.307-2.322 \AA)$ and $\mathrm{Pt}\left(\mathrm{PPh}_{3}\right)_{3}(\mathrm{Pt}-\mathrm{P} 2.262-2.271 \AA)$ [45] and essentially linear 2-coordination for $\mathbf{M}\left(\mathrm{PBu}_{2}^{\mathrm{t}} \mathrm{Ph}\right)_{2}(\mathbf{M}=\mathrm{Pd}, \mathrm{Pt} ; \mathbf{M}-\mathbf{P}$ 2.285 and $2.252 \AA$, respectively), $\mathrm{M}\left(\mathrm{Pcy}_{3}\right)_{2}(\mathrm{Pd}-\mathrm{P} 2.26 \AA, \mathrm{Pt}-\mathrm{P} 2.231 \AA)$ and $\mathrm{Pd}\left(\mathrm{PBu}_{3}^{\mathrm{t}}\right)_{2}(\mathrm{Pd}-\mathrm{P} 2.285 \AA)$. The last named has a $\mathrm{P}-\mathrm{Pd}-\mathrm{P}$ angle of $180^{\circ}$ while the $\mathrm{PBu}_{2}^{\mathrm{t}} \mathrm{Ph}$ complexes are virtually linear but with some short metal ortho-hydrogen contacts. Curiously, the $\mathrm{Pcy}_{3}$ complexes have

Figure 3.11 The structure of $\mathrm{Pd}\left(\mathrm{Pcy}_{3}\right)_{2}$. (Reproduced with permission from J. Chem. Soc., Chem. Commun., 1974, 400.)
significantly 'bent' $\mathrm{P}-\mathrm{M}-\mathrm{P}$ bonds ( $158.4^{\circ} \mathrm{M}=\mathrm{Pd} ; 160.5^{\circ} \mathrm{M}=\mathrm{Pt}$ ) (Figure 3.11). $\mathrm{Pd}\left(\mathrm{P}(o \text {-tolyl })_{3}\right)_{2}$ has linear $\mathrm{P}-\mathrm{Pd}-\mathrm{P}$ coordination [46].

As expected, the $\mathrm{Pt}-\mathrm{P}$ bond increases from $2.231 \AA$ in the 2 -coordinate $\mathrm{Pt}\left(\mathrm{Pcy}_{3}\right)_{2}$ to $2.303 \AA$ in 3-coordinate $\mathrm{Pt}\left(\mathrm{Pcy}_{3}\right)_{3}$. (Similarly in $\mathrm{Pd}\left(\mathrm{PPh}_{3}\right)_{n}$ $(n=3,4)$, from $2.31 \AA(n=3)$ to $2.443 \AA(n=4)$.)

Most of these compounds are solids (though a few such as $\mathrm{Pt}\left(\mathrm{PEt}_{3}\right)_{3}$, $\mathrm{Pt}\left(\mathrm{PBu}_{3}^{\mathrm{n}}\right)_{3}$ and $\mathrm{Pt}\left(\mathrm{PF}_{3}\right)_{4}$ are oils at room temperature). Their stoichiometry in solution has been studied, most particularly by ${ }^{31} \mathrm{P}$ NMR at low temperatures, to determine which species are present [47]. Table 3.8 shows that the coordination number is principally determined by the bulk of the ligand

(conveniently measured in terms of its cone angle), i.e. the bulkier the ligand, the lower the coordination number of the complex isolated.

Steric requirements also affect the stability of compounds; therefore, for the complexes $\mathrm{Pt}\left(\mathrm{PR}_{3}\right)_{4}$, the $\mathrm{PEt}_{3}$ complex (cone angle $132^{\circ}$ ) loses 1 mol phosphine in vacuo at $50^{\circ} \mathrm{C}$, but the $\mathrm{PMe}_{3}$ complex (cone angle $118^{\circ}$ ) is unaffected.

Steric factors are not the only ones to affect stability; $\mathrm{Ni}\left(\mathrm{Pcy}_{3}\right)_{3}$ does not dissociate, while $\mathbf{M}\left(\mathrm{Pcy}_{3}\right)_{2}(\mathbf{M}=\mathbf{P d}, \mathbf{P t})$ is stable, the reverse of what would be expected on steric grounds. Similarly with $\mathrm{P}(o \text {-tolyl })_{3}$, nickel forms $\mathrm{NiL}_{4}$ while platinum forms $\mathrm{PtL}_{3}$. Such discrepancies may be accounted for by taking into account the electron-donating power (basicity) of the phosphine and the electronic properties of the metal; thus electrondonating phosphines like $\operatorname{PPr}_{3}^{\mathrm{i}}$ can satisfy the electron demand of the metal better than aryl phosphines such as $\mathrm{P}(\mathrm{O} \text {-o-tolyl })_{3}$ [48]. Compression of the cone angle or meshing of the ligands may also be important [45c]. Tricyclohexylphosphine has a cone angle of $170^{\circ}$ yet meshing of the ligands leads to the isolability of $\mathrm{Pt}\left(\mathrm{Pcy}_{3}\right)_{3}$ from solution at $-15^{\circ} \mathrm{C}$ (only $\mathrm{Pt}\left(\mathrm{Pcy}_{3}\right)_{2}$ is detected in solution above $0^{\circ} \mathrm{C}$ ). Corresponding palladium and platinum complexes generally resemble each other closely, but there are differences; $\mathrm{Pd}\left(\mathrm{PPh}_{2} \mathrm{Me}\right)_{4}$ does not dissociate while the platinum analogue does. $\mathrm{Pd}\left(\mathrm{PBu}_{2}^{\mathrm{t}} \mathrm{Ph}\right)_{2}$ binds oxygen reversibly, the platinum analogue binds irreversibly; $\mathrm{PtL}_{2}\left(\mathrm{~L}=\mathrm{PPr}_{3}^{\mathrm{i}}, \mathrm{Pcy}_{3}, \mathrm{PBu}_{2}^{\mathrm{t}} \mathrm{Ph}\right)$ adds hydrogen reversibly whereas the palladium analogues do not.

In these compounds, compared with the palladium and platinum complexes, nickel generally exhibits higher coordination numbers, an effect similar to that seen with copper and silver compared with gold (section 4.1). Consideration of the $d-s$ and $s-p$ separations (Table 3.9) suggests that 2 -coordination may be favoured for large $\mathrm{s}-\mathrm{p}$ or small $\mathrm{d}-\mathrm{s}$ separations (while relativistic effects may be significant for platinum, the general similarity between platinum and palladium suggests that it is not an important factor).

In addition to the tertiary phosphine complexes, a few others such as $\mathrm{Pt}\left(\mathrm{QBu}_{3}\right)_{4}(\mathrm{Q}=\mathrm{As}, \mathrm{Sb})$ and $\mathrm{Pt}\left(\mathrm{QPh}_{3}\right)_{4}$ have been made, but they have been the subjects of few studies.

Compounds $\mathrm{M}\left(\mathrm{PPh}_{3}\right)_{2}(\mathrm{M}=\mathrm{Pd}, \mathrm{Pt})$ have been postulated as kinetic intermediates but controversy has surrounded their isolation. It seems some ' $\mathrm{M}\left(\mathrm{PPh}_{3}\right)_{2}$ ' species reported could have been $\mathrm{M}\left(\mathrm{PPh}_{3}\right)_{2} \mathrm{~L}\left(\mathrm{~L}\right.$, e.g. $\mathrm{H}_{2}$,

Table 3.9 Values for $d-s$ and $s-p$ separations ( eV )

|  | $\mathrm{d}^{10}-\mathrm{d}^{9} \mathrm{~s}$ | $\mathrm{~d}^{9} \mathrm{~s}-\mathrm{d}^{9} \mathrm{p}$ | $\mathrm{d}^{10}-\mathrm{d}^{9} \mathrm{p}^{1}$ |
| :---: | :---: | :---: | :---: |
| Ni | -1.8 | 3.52 | 1.72 |
| Pd | 0.81 | 3.42 | 4.23 |
| Pt | 0.76 | 4.04 | 3.28 |

Figure 3.12 Complexes produced by refluxing solutions of $\mathrm{Pt}\left(\mathrm{PPh}_{3}\right)_{4}$.
$\mathrm{N}_{2}, \mathrm{C}_{2} \mathrm{H}_{4}$ ) or internally metallated species. Reactions such as extended refluxing of $\mathrm{Pt}\left(\mathrm{PPh}_{3}\right)_{4}$ in benzene yields clusters [49] (Figure 3.12).

Recently, however, $\mathrm{Pd}\left(\mathrm{PPh}_{3}\right)_{2}$ has been reported to result from reduction of palladium(II) complexes as a very reactive yellow solid [50]:

$$
\mathrm{Pd}\left(\mathrm{C}_{3} \mathrm{H}_{5}\right)\left(\mathrm{PPh}_{3}\right)_{2}^{+} \xrightarrow{\mathrm{Ph}_{2} \mathrm{MeSiLi}} \mathrm{Pd}\left(\mathrm{PPh}_{3}\right)_{2}
$$

Electrochemical reduction of cis- $\mathrm{PtCl}_{2}\left(\mathrm{PR}_{3}\right)_{2}(\mathrm{R}=\mathrm{Ph}, \mathrm{Et})$ generates very reactive $\mathrm{Pt}\left(\mathrm{PR}_{3}\right)_{2}$ species [51] (though it has been suggested that corresponding palladium compounds may be anionic, e.g. $\left.\mathrm{Pd}\left(\mathrm{PR}_{3}\right)_{2} \mathrm{Cl}_{2}^{2-}\right)$

$$
\mathrm{Pt}\left(\mathrm{PR}_{3}\right)_{2} \mathrm{Cl}_{2} \xrightarrow{2 \mathrm{e}^{-}} \mathrm{Pt}\left(\mathrm{PPR}_{3}\right)_{2}+2 \mathrm{Cl}^{-}
$$

They can be trapped by reactive molecules

$$
\mathrm{Pt}\left(\mathrm{PEt}_{3}\right)_{2} \xrightarrow[\mathrm{X}=\mathrm{Cl}, \mathrm{CN}]{\mathrm{PhX}} \operatorname{trans}-\mathrm{Pt}(\mathrm{Ph}) \mathrm{X}\left(\mathrm{PEt}_{3}\right)_{2}
$$

UV irradiation of $\mathrm{Pt}\left(\mathrm{PEt}_{3}\right)_{2}\left(\mathrm{C}_{2} \mathrm{O}_{4}\right)$ under a dihydrogen atmosphere yields a hydride by trapping [52]:

$$
\mathrm{Pt}\left(\mathrm{PEt}_{3}\right)_{2} \mathrm{C}_{2} \mathrm{O}_{4} \xrightarrow{h \nu} \mathrm{Pt}\left(\mathrm{PEt}_{3}\right)_{2}+2 \mathrm{CO}_{2} \xrightarrow{\mathrm{H}_{2}} \text { trans }-\mathrm{PtH}_{2}\left(\mathrm{PEt}_{3}\right)_{2}
$$

Thermolysis of cis $-\mathrm{PtH}\left(\mathrm{CH}_{2} \mathrm{CMe}_{3}\right)\left(\mathrm{cy}_{2} \mathrm{PC}_{2} \mathrm{H}_{2} \mathrm{Pcy}_{2}\right)$ at $45-80^{\circ} \mathrm{C}$ yields a bent platinum( 0 ) complex (Figure 3.13) that is intensely reactive to a whole range of unactivated $\mathrm{C}-\mathrm{H}$ bonds in saturated and unsaturated hydrocarbons.

Figure 3.13 Addition reactions of $\mathrm{Pt}\left(\mathrm{cy}_{2} \mathrm{PCH}_{2} \mathrm{CH}_{2} \mathrm{Pcy}_{2}\right)$.

Figure 3.14 Zerovalent complexes of polydentate phosphines.

Zerovalent complexes are also obtained with polydentate phosphines [53]:

$$
\begin{aligned}
& \mathrm{Pd}_{2} \mathrm{Cl}_{2}(\mathrm{dppm})_{2} \xrightarrow[\text { exc. dppm }]{\mathrm{NaBH}_{4}} \mathrm{Pd}_{2}(\mathrm{dppm})_{3} \\
& \quad \mathrm{PtCl}_{2}(\mathrm{cod}) \xrightarrow{\mathrm{dppp}} \mathrm{PtCl}_{2}(\mathrm{dppp}) \xrightarrow[\mathrm{NaBH}_{4}]{\mathrm{dppp}} \mathrm{Pd}(\mathrm{dppp})_{2}
\end{aligned}
$$

Their structures are shown in Figure 3.14.

### 3.6.2 Reactions of $\operatorname{Pt}\left(P \mathrm{Ph}_{3}\right)_{\mathrm{n}}$ and related species

$\mathrm{Pt}\left(\mathrm{PPh}_{3}\right)_{n}(n=3,4)$ species [54] have been studied with profit for many years; they undergo a wide range of addition reactions with attendant loss of phosphine, the kinetically active species probably being $\operatorname{Pt}\left(\mathrm{PPh}_{3}\right)_{2}$. (The palladium analogues generally behave similarly but are much less studied.)

Though many of the products shown in Figure 3.15 are clearly platinum(II) species, some are formally platinum(0).

However, it seems that these are best viewed as platinum(II) species too, so that two-electron metal-to-ligand transfer has been effected. The structures of $\mathrm{Pt}\left(\mathrm{PPh}_{3}\right)_{2} \mathrm{Z}\left(\mathrm{Z}=\eta^{2}-\mathrm{O}_{2}, \eta^{2}-\mathrm{C}_{3} \mathrm{H}_{4}, \eta^{2}-\mathrm{CS}_{2}\right)$ (Figure 3.16) all involve 'square planar' coordination as expected for platinum(II) rather than the tetrahedral 4-coordination anticipated for platinum( 0 ).

Similarly, ESCA data show the platinum $4 \mathrm{f}_{7 / 2}$ binding energy in $\mathrm{Pt}\left(\mathrm{PPh}_{3}\right)_{2} \mathrm{O}_{2}(73.2 \mathrm{eV})$ to be nearer to that in $\mathrm{Pt}\left(\mathrm{PPh}_{3}\right)_{2} \mathrm{Cl}_{2}(73.4 \mathrm{eV})$ rather than $\mathrm{Pt}\left(\mathrm{PPh}_{3}\right)_{4}(71.7 \mathrm{eV})$ or platinum metal $(71.2 \mathrm{eV})$ [55]. Like many of the rhodium and iridium dioxygen adducts (section 2.11) adduct formation with $\mathrm{O}_{2}$ is irreversible (though that with $\mathrm{SO}_{2}$ is reversed on heating). With unsaturated compounds (alkenes, alkynes, benzene) $\eta^{2}$-coordination is the rule. Reactions with alkyl and some aryl halides affords a route to mono alkyls and aryls. The reactions with halogens gives a route to cis$\mathrm{Pt}\left(\mathrm{PPh}_{3}\right)_{2} \mathrm{X}_{2}(\mathrm{X}=\mathrm{Br}, \mathrm{I})$; if an excess of halogen is used and the reaction stopped after a few minutes (to prevent oxidation to platinum(IV)) the initial trans-product is isolated (the halogen oxidizes liberated $\mathrm{PPh}_{3}$ and prevents it catalysing, as occurs so often with platinum(II), the trans-cis isomerization). Other reactions can involve coupling (NO) and decoupling $\left(\mathrm{C}_{2} \mathrm{~N}_{2}\right)$.

Figure 3.15 Reactions of $\left[\mathrm{Pt}\left(\mathrm{PPh}_{3}\right)_{n}\right]$.
The $\mathrm{O}_{2}$ adduct has a rich chemistry of its own (Figure 3.15) reacting with small electrophiles in processes involving oxidation of the substrate. Thus NO couples to give nitrite and $\mathrm{N}_{2} \mathrm{O}_{4}$ nitrate; $\mathrm{SO}_{2}$ is turned into sulphate and $\mathrm{CO}_{2}$ into carbonate. In several cases, as with aldehydes and ketones, a peroxychelate ring results.

Other zerovalent phosphine complexes sometimes exhibit different reactions. $\mathrm{Pt}\left(\mathrm{PPh}_{3}\right)_{3}$ does not react with dihydrogen but $\mathrm{Pt}\left(\mathrm{PEt}_{3}\right)_{3}$ forms $\mathrm{Pt}\left(\mathrm{PEt}_{3}\right)_{3} \mathrm{H}_{2}$. $\mathrm{Pt}\left(\mathrm{PR}_{3}\right)_{3}\left(\mathrm{R}=\mathrm{Et}, \mathrm{Pr}^{\mathrm{i}}\right)$ adds $\mathrm{H}_{2} \mathrm{O}$ to form hydroxybases $\left[\mathrm{Pt}\left(\mathrm{PEt}_{3}\right)_{3} \mathrm{H}^{+} \mathrm{OH}\right]^{-}$ and $\left[\mathrm{Pt}\left(\mathrm{PPr}_{3}^{\mathrm{i}}\right)_{2} \mathrm{H}\right.$ (solvent $\left.)\right]^{+} \mathrm{OH}^{-} . \mathrm{Pd}\left(\mathrm{Pcy}_{3}\right)_{2}$ reacts with the strong acid $\mathrm{HBF}_{4}$ to give trans- $\left[\mathrm{Pd}\left(\mathrm{Pcy}_{3}\right)_{2} \mathrm{H}\left(\mathrm{H}_{2} \mathrm{O}\right)\right]^{+} \mathrm{BF}_{4}^{-}$and with carboxylic acids to form $\left[\mathrm{Pd}\left(\mathrm{Pcy}_{3}\right)_{2} \mathrm{H}(\mathrm{OCOR})\right]$; with phenols it gives $\left[\mathrm{Pd}\left(\mathrm{Pcy}_{3}\right)_{2} \mathrm{H}\left(\mathrm{OC}_{6} \mathrm{X}_{5}\right)\right]$

Figure 3.16 Structures of $\mathrm{Pt}\left(\mathrm{PPh}_{3}\right)_{2} \mathrm{Z}\left(\mathrm{Z}=\mathrm{O}_{2}, \mathrm{CS}_{2}, \mathrm{C}_{3} \mathrm{H}_{4}\right)$.

Figure 3.17 A comparison between the geometeries of $\left[\mathrm{Pt}\left(\mathrm{PBu}_{2}^{\mathrm{t}} \mathrm{Ph}\right)_{2}\right]$ and $\left[\mathrm{Pt}\left(\mathrm{PBu}_{2}^{\mathrm{t}} \mathrm{Ph}\right)_{2}\left(\mathrm{O}_{2}\right)\right]$.
( $\mathrm{X}=\mathrm{H}, \mathrm{F}$ ). The platinum analogue behaves similarly, and it also reacts with $\mathrm{H}_{2}$ to form trans $-\mathrm{Pt}\left(\mathrm{Pcy}_{3}\right)_{2} \mathrm{H}_{2}$.

Both $\mathrm{M}\left(\mathrm{PPhBu}_{2}^{\mathrm{t}}\right)_{2}$ compounds $(\mathrm{M}=\mathrm{Pd}, \mathrm{Pt})$ add $\mathrm{O}_{2}$, the former reversibly. They are nearly isostructural, with a slightly longer $\mathrm{O}-\mathrm{O}$ bond in the platinum compound $(1.43 \AA)$ than in the palladium analogue $(1.37 \AA)$. Compared with the parent platinum compound (Figure 3.17) the $\mathrm{Pt}-\mathrm{P}$ bonds are some $0.04 \AA$ longer in the dioxygen compound, but though the $\mathrm{P}-\mathrm{Pt}-\mathrm{P}$ angle has closed from $180^{\circ}$ to $113.1^{\circ}$, this is a good deal larger than the value in the $\mathrm{PPh}_{3}$ analogue ( $101^{\circ}$ ) and suggests steric crowding.

The adoption of a planar structure in these adducts, rather than the sterically more favourable tetrahedral one, is in keeping with a platinum(II) oxidation state. The side-on bonding of the $\mathrm{O}_{2}$ molecule is believed to involve two components, as in Zeise's salt (Figure 3.18).

There is (a) $\sigma$-donation from a filled oxygen orbital to an empty platinum orbital and (b) $\pi$ back-bonding from a filled metal $d$ orbital into an empty oxygen $\pi^{*}$-anti-bonding orbital.

There has been considerable study of reactivity patterns and reaction mechanisms for oxidative additions of $\mathrm{Pt}\left(\mathrm{PR}_{3}\right)_{n}$ species. Reactivity is determined by (a) steric factors, thus complexes like $\mathrm{Pt}\left(\mathrm{Pcy}_{3}\right)_{2}$ are very reactive and (b) the basicity of the phosphine. The more basic the phosphine, the more facile is oxidative addition; therefore $\mathrm{Pt}\left(\mathrm{PEt}_{3}\right)_{3}$ will add PhCl and PhCN while the less nucleophilic $\mathrm{Pt}\left(\mathrm{PPh}_{3}\right)_{3}$ will not. It is thought that many of these reactions involve initial dissociation of a phosphine, as in the addition of benzyl halides to $\mathrm{Pd}\left(\mathrm{PPh}_{3}\right)_{4}$, proceeding generally by inversion through a $\mathrm{S}_{\mathrm{N}} 2$ mechanism. Either ionic or radical mechanisms are possible. Radical pathways can be detected in three ways:

Figure 3.18 Metal-dioxygen bonding in platinum-dioxygen complexes.

1. Addition of radical inhibitors (e.g. duroquinone, galvinoxyl), which will slow up any pathway involving radicals.
2. Adding a radical trap like $\mathrm{Bu}^{\mathrm{t}} \mathrm{NO}$ to the reaction mixture; this reacts with radicals ( $\mathrm{R}^{*}$ ) forming nitroxide radicals $\mathrm{Bu}^{t}\left(\mathrm{R}^{\circ}\right) \mathrm{NO}$ that can be detected by ESR.
3. Observation of CIDNP effects in the resonances of either reactant or product species in the NMR spectrum of the reaction mixture.

In the case of the reaction of $\mathrm{PhCH}_{2} \mathrm{Br}$ with $\mathrm{Pt}\left(\mathrm{PEt}_{3}\right)_{3}$, it is thought that $\mathrm{Pt}\left(\mathrm{PEt}_{3}\right)_{2}\left(\mathrm{PhCH}_{2}\right) \mathrm{Br}$ is formed via a $\mathrm{S}_{\mathrm{N}} 2$ route where the platinum forms a cationic complex that undergoes immediate attack by $\mathrm{Br}^{-}$while some $\mathrm{Pt}\left(\mathrm{PEt}_{3}\right)_{2} \mathrm{Br}_{2}$ is formed in a very rapid reaction unaffected by radical scavengers.

$$
\begin{aligned}
\mathrm{Pt}\left(\mathrm{PEt}_{3}\right)_{3}+\mathrm{PhCH}_{2} \mathrm{Br} & \rightarrow \mathrm{Pt}^{\mathrm{I}}\left(\mathrm{PEt}_{3}\right)_{n} \mathrm{Br}+\mathrm{PhCH}_{2}^{\cdot} \\
\mathrm{Pt}\left(\mathrm{PEt}_{3}\right)_{n} \mathrm{Br}+\mathrm{BrCH}_{2} \mathrm{Ph} & \rightarrow \mathrm{Pt}\left(\mathrm{PEt}_{3}\right)_{2} \mathrm{Br}_{2}+\mathrm{PhCH}_{2}{ }^{\circ}
\end{aligned}
$$

This is in contrast with the reaction of $\mathrm{Pt}\left(\mathrm{PEt}_{3}\right)_{3}$ with $\mathrm{Me}_{3} \mathrm{CCH}_{2} \mathrm{Br}$, which is affected by radical scavengers like galvinoxyl, where the radicals are sufficiently long lived to undergo side reactions with the solvent - in toluene, some $\mathrm{Pt}\left(\mathrm{PEt}_{3}\right)_{2}\left(\mathrm{PhCH}_{2}\right) \mathrm{Br}$ is formed - giving credence to a radical chain mechanism. In the reactions of alkyl halides (EtI, MeI, $\mathrm{PhCH}_{2} \mathrm{Br}$ ) to $\mathrm{Pt}\left(\mathrm{PPh}_{3}\right)_{3}$, believed to proceed by a non-chain radical process, addition of radical traps results in the formation of ESR-active radicals. This reaction is very solvent dependent; in benzene MeI adds to give solely $\mathrm{Pt}\left(\mathrm{PPh}_{3}\right)_{2} \mathrm{MeI}$ while in THF $\mathrm{Pt}\left(\mathrm{PPh}_{3}\right)_{2} \mathrm{I}_{2}$ is the main product [56]. A detailed study of this reaction in benzene shows that the most important steps are

$$
\begin{aligned}
\mathrm{Pt}\left(\mathrm{PPh}_{3}\right)_{3} & \rightleftharpoons \mathrm{Pt}\left(\mathrm{PPh}_{3}\right)_{2}+\mathrm{PPh}_{3} \\
\mathrm{Pt}\left(\mathrm{PPh}_{3}\right)_{2}+\mathrm{MeI} & \rightarrow \mathrm{Pt}\left(\mathrm{PPh}_{3}\right)_{2}(\mathrm{Me}) \mathbf{I}+\mathrm{PPh}_{3}
\end{aligned}
$$

Undissociated $\mathrm{Pt}\left(\mathrm{PPh}_{3}\right)_{3}$ is much less reactive.
Addition of RX to a $\operatorname{Pt}\left(\mathrm{PR}_{3}\right)_{n}$ species may occur by two main pathways:

1. $\mathrm{S}_{\mathrm{N}} 2$ attack of the electron-rich platinum( 0 ) on the alkyl halide to give the $\mathrm{Pt}^{11}(\mathrm{R}) \mathrm{X}$ species directly, possibly via an ionic intermediate.
2. Platinum removes a halogen atom from the halide, causing homolytic fission of the C -halogen bond. The resulting $\mathrm{Pt}^{\mathrm{I}}-\mathrm{XR}$ radical pair can either react to form $\mathrm{Pt}^{\mathrm{II}}(\mathrm{R}) \mathrm{X}$ or separate, with subsequent reaction with RX leading to either $\mathrm{PtX}_{2}$ or PtRX species or reaction with solvent molecules.

### 3.6.3 Carbonyl complexes

$\mathrm{Ni}(\mathrm{CO})_{4}$ is a most important nickel carbonyl compound and can even be prepared directly from its constituents yet the corresponding palladium
and platinum compounds do not exist (at least, at room temperature). If platinum (or palladium) is vaporized from a hot rod (around $1800^{\circ} \mathrm{C}$ ) to produce gaseous platinum atoms, and co-condensed with CO in an argon matrix, IR spectra indicate the presence of metal carbonyl species $\mathrm{M}(\mathrm{CO})_{x}$ ( $x=1-4$ ). On controlled warming, diffusion takes place with successive CO addition taking place to yield $\mathrm{M}(\mathrm{CO})_{4}$ as the stablest product ( $\nu(\mathrm{C}-\mathrm{O})$ 2052, $2070,2053 \mathrm{~cm}^{-1}$ for nickel, palladium and platinum tetracarbonyls, respectively). Analysis of spectra leads to metal-carbon force constants of $1.80,0.82$ and $1.28 \mathrm{mdyn} \AA^{-1}$ for nickel, palladium and platinum tetracarbonyls, respectively. This indicates the weakness of the $\mathrm{Pd}-\mathrm{C}$ and $\mathrm{Pt}-\mathrm{C}$ bonds; they decompose if the matrices are warmed above $c .80 \mathrm{~K}$ [57, 58].

The $\mathrm{M}-\mathrm{CO}$ bond is stabilized by the presence of tertiary phosphines

$$
\begin{gathered}
\mathrm{Pt}\left(\mathrm{PPh}_{3}\right)_{3}+\mathrm{CO} \xrightarrow{\mathrm{Me}_{2} \mathrm{CO}} \mathrm{Pt}\left(\mathrm{PPh}_{3}\right)_{3} \mathrm{CO} \\
\mathrm{PtCl}_{2}+2 \mathrm{PPh}_{3}+2 \mathrm{CO}+\mathrm{Zn} \xrightarrow{\mathrm{ZnCl}}{ }_{2}+\mathrm{Pt}\left(\mathrm{PPh}_{3}\right)_{2}(\mathrm{CO})_{2}
\end{gathered}
$$

Both $\mathrm{Pt}\left(\mathrm{PPh}_{3}\right)_{3} \mathrm{CO}$ and $\mathrm{Pt}\left(\mathrm{PPh}_{2} \mathrm{Et}\right)_{2}(\mathrm{CO})_{2}$ have essentially tetrahedral coordination of platinum.

The reason for the greater stability of $\mathrm{M}\left(\mathrm{PR}_{3}\right)_{n}$ over $\mathrm{M}(\mathrm{CO})_{4}$ must lie in the difference in donor characteristics of the two kinds of ligand. CO is a poor $\sigma$-donor but a strong $\pi$-acceptor, while tertiary phosphines are much better $\sigma$-donors.

In a binary carbonyl both $\sigma$ - and $\pi$-components are important in the metal-carbon bond: a $\sigma$-bond owing to $\mathrm{M} \leftarrow \mathrm{C}$ donation and a $\pi$-bond owing to back-bonding from filled metal d orbitals to empty $\mathrm{CO} \pi^{*}$-orbitals. The relative energies of the metal $d$ orbitals are in the order of $4 \mathrm{~d}(\mathrm{Pd})>5 \mathrm{~d}(\mathrm{Pt})>3 \mathrm{~d}(\mathrm{Ni})$ so that the strength of the $\sigma$-component would be in the order of $\mathrm{Pd}<\mathrm{Pt}<\mathrm{Ni}$ (this also correlates with the electronegativities of the metals). The ability of the metal to donate electrons may correlate with the ionization energies; $I_{1}$ values are $737(\mathrm{Ni}), 805(\mathrm{Pd})$ and $870(\mathrm{Pt}) \mathrm{kJ} \mathrm{mol}^{-1}$, giving a $\pi$-bonding order $\mathrm{Pt}<\mathrm{Pd} \ll \mathrm{Ni}$. Therefore, on both grounds the $\mathrm{Ni}-\mathrm{C}$ bond is predicted to be the strongest.

### 3.6.4 Carbonyl clusters

Apart from the mixed phosphine/carbonyl species $\mathrm{Pt}\left(\mathrm{PPh}_{3}\right)_{4-n}(\mathrm{CO})_{n}$ ( $n=1,2$ ), there are polynuclear species $\mathrm{Pt}_{3} \mathrm{~L}_{n}(\mathrm{CO})_{3}\left(n=3,4 ; \mathrm{L}=\mathrm{PR}_{3}\right)$, and additionally some remarkable anionic binary carbonyl clusters, formed by reductive carbonylation of $\mathrm{Na}_{2} \mathrm{PtCl}_{6} \cdot 6 \mathrm{H}_{2} \mathrm{O}$ with general formulae $\left[\mathrm{Pt}_{3}(\mathrm{CO})_{6}\right]_{n}^{2-}$. These contain $\mathrm{Pt}_{3}(\mathrm{CO})_{3}\left(\mu^{2}-\mathrm{CO}\right)_{3}$ clusters stacked along a three-fold axis but with a twist or sliding minimizing repulsions in adjacent layers [59].

### 3.6.5 Isocyanide complexes

A few isocyanides of palladium and platinum are known in the zerovalent oxidation state. The best characterized compounds involve triangular $\mathbf{M}_{3}$ clusters with $\mathrm{M}-\mathrm{M}$ bonds.

$$
\begin{gathered}
\operatorname{Pt}\left(\mathrm{PBu}_{3}^{\mathrm{t}}\right)_{2} \xrightarrow{\mathrm{Bu} \mathrm{NC}}\left[\mathrm{Pt}\left(\mathrm{CNBu}^{\mathrm{t}}\right)_{2}\right]_{3} \\
\mathrm{Pt}(\mathrm{cod})_{2} \xrightarrow{\mathrm{Pr}^{\prime} \mathrm{NC}}\left[\mathrm{Pt}\left(\mathrm{CNPr}^{\mathrm{i}}\right)_{2}\right]_{3}
\end{gathered}
$$

The palladium compound $\left[\mathrm{Pd}(\mathrm{CNcy})_{2}\right]_{3}$ has been made by metal vapour synthesis, from Pd atoms and a solution of cyNC at 160 K . It has an analogous structure $\left[\mathrm{Pd}_{3}(\mathrm{CNcy})_{3}\left(\mu^{2}-\mathrm{CNcy}\right)_{3}\right][60]$.

### 3.7 Palladium(I) and platinum(I) compounds

A limited chemistry of the +1 oxidation state of palladium and platinum has developed since the 1970s, mainly involving metal-metal bonded dinuclear complexes [61].

### 3.7.1 Phosphine complexes

Phosphine complexes can be synthesized by reduction or reproportionation. Complexes of dppm are the most important and can undergo both substitution reactions and insertions (Figure 3.19).

Using a 2-diphenylphosphinopyridine as the bridging ligand (with a similar 'bite' to dppm) leads to a similar dimer (Figure 3.20).

Figure 3.19 Synthesis and reactions of palladium(I) bis(diphenylphosphino)methane complexes.

Figure 3.20 A palladium(I) 2-diphenylphosphinopyridine complex.
Hydrogen reduction of (dppp) $\mathrm{Pd}\left(\mathrm{CF}_{3} \mathrm{SO}_{3}\right)_{2}(\mathrm{dppp}) \mathrm{Ph}_{2} \mathrm{P}\left(\mathrm{CH}_{2}\right)_{3} \mathrm{PPh}_{2}$ affords [dpppPd] $2_{2}\left(\mathrm{CF}_{3} \mathrm{SO}_{3}\right)_{2}$, which has agonistic Pd -phenyl interactions as well as normal $\mathrm{Pd}-\mathrm{P}$ coordination and a $\mathrm{Pd}-\mathrm{Pd}$ bond ( $2.701 \AA$ ) (Figure 3.21).

Several cis-platinum(II) dihydrides lose $\mathrm{H}_{2}$ reversibly in solution, forming dinuclear platinum(I) hydrides [(diphosphine) PtH$]_{2}[62]$.

Isocyanide complexes can also be made by reproportionation.

### 3.7.2 Isocyanide complexes

Isocyanide complexes can be synthesized by:

$$
\left.\begin{array}{rl}
\mathrm{PdX} & \left(\mathrm{Bu}^{\mathrm{t} N C}\right)_{2}+\mathrm{Pd}\left(\mathrm{Bu}^{\mathrm{t}} \mathrm{NC}\right)_{2}
\end{array} \quad \rightarrow\left[\mathrm{PdX}\left(\mathrm{Bu}^{\mathrm{t}} \mathrm{NC}\right)_{2}\right]_{2}\right)
$$

The methylisocyanide complex has a dimeric structure with a direct metalmetal bond ( $2.531 \AA$ ) and only terminal isocyanides, in a staggered configuration (Figure 3.22).

The platinum analogue is similarly made.

Figure 3.21 Structure of the dimeric palladium $(\mathrm{I})$ complex $\left[(\mathrm{dppp}) \mathrm{Pd}_{2}\left(\mathrm{CF}_{3} \mathrm{SO}_{3}\right)_{2}\right.$. (Reprinted with permission from Organometallics, 1992, 11, 23. Copyright (1992) American Chemical Society.)

Figure 3.22 The staggered structure of $\left[\mathrm{Pd}_{2}(\mathrm{MeNC})_{6}\right]^{2+}$.

### 3.8 Complexes of palladium(II) and platinum(II)

A wide variety of complexes are formed by both metals in the +2 oxidation state; indeed, it is the most important one for palladium. The complexes can be cationic, neutral or anionic. Both $\mathrm{Pd}^{2+}$ and $\mathrm{Pt}^{2+}$ are 'soft' acids so that many stable complexes are formed with S or P as donor atoms but few with O-donors, though there are important ammines. There are pronounced similarities between corresponding palladium and platinum complexes; the latter are more studied (and less labile).

### 3.8.1 Complexes of O-donors

Complexes of O-donors are relatively rare, explicable by the 'soft' nature of the divalent ions. A telling indication is that sulphoxide ligands will only bind through O if steric effects make S -bonding impractical. The most important complexes are diketonates and carboxylates (for the aqua ions see section 3.5).

## Diketonates

Two kinds of platinum diketonate may be made

$$
\begin{aligned}
\mathrm{PtCl}_{4}^{2-}+\mathrm{MeCOCH}_{2} \mathrm{COMe} \xrightarrow{\mathrm{KOH}} \mathrm{KPtCl}(\mathrm{acac})_{2} \\
\underset{\text { exc. } \mathrm{MeCOCH}}{2} \mathrm{COMe} \\
\mathrm{KOH} \\
\mathrm{Ct}(\mathrm{acac})_{2}
\end{aligned}
$$

$\mathrm{Pt}(\mathrm{acac})_{2}$ has the expected square planar coordination by oxygen $(\mathrm{Pt}-\mathrm{O}$ $1.979-2.008 \AA$ ) with bidentate diketonates; this has also been confirmed for $\mathrm{Pd}(\mathrm{PhCOCHCOMe})_{2}$, which is obtainable as cis- and trans-isomers that can be crystallized and separated manually (Figure 3.23).

In $\left[\mathrm{PtCl}(\mathrm{acac})_{2}\right]^{-}, 4$-coordination is possible because one of the diketonates is C-bonded (Figure 3.24).

The diketonates can form Lewis base adducts such as 5-coordinate $\mathrm{Pd}[\mathrm{P}(o-$ tolyl $\left.)_{3}\right]\left(\mathrm{CF}_{3} \mathrm{COCHCOCF}_{3}\right)_{2}$ (Figure 3.25 ), though with acetylacetone square planar adducts of the type $\mathrm{M}(\mathrm{acac})_{2}\left(\mathrm{PR}_{3}\right)_{2}$ are usually obtained, where the diketone is monodentate O -bonded [63].
