

Top Tools for Admins

MacRetreats 2005

Scott M. Neal
Senseption

Goal of Session

- Empower non-programmers to utilize developer tools to solve problems
 - Develop a clear understanding of OS X's primary configuration file format: Property Lists
 - Utilize existing command-line tools with a GUI that YOU develop
 - Automate repeated tasks that would normally be boring and prone to error
 - More spare time for you!
- This session is designed with walk-through examples for you to follow
 - Hopefully you've already installed the developer tools!

Developer Tools will Improve Our Lives

- Problems we will solve today with Developer Tools
 - Property Lists and User Defaults editing
 - Creating Repeated tasks using `launchd`
 - Prettying-up shell scripts and commands by adding a GUI
 - Automating menial tasks

Developing on OS X

- Cocoa
 - Interface Builder
- Carbon
 - Interface Builder
- WebObjects
 - OModel
 - WebObjects Builder
- Java
- BSD-compliant UNIX code
 - commercial compilers
 - X11

Developing on OS X: Tools in this Session

- Applescript
 - Script Editor
- Applescript Studio
 - Interface Builder
- Automator
 - Automator (from the department of redundancy department)

XCode

- Development environment provided with OS X Developer Tools
- Provides templates for projects
 - Initial configuration files
 - Organized structure that is project type-specific
 - VERY configurable

Property Lists & Defaults

- Configuration information for processes needs to be stored somewhere
- Apple developed the Property List (aka plist) Format to provide a consistent way to store information
 - Not ALL configuration information is stored in plist format
- Property Lists provide the backbone for the Defaults Preference infrastructure

Property Lists & Defaults

- Keys are specific to each process and define configuration options for that process, such as
 - Default new window location and size
 - File location/path
 - *the sky is the limit...*
- Modifying Property Lists and the Defaults system gives YOU control over the operation of processes
- Great for troubleshooting/debugging
 - “Trashing the preferences” (which really should be “Renaming the preferences”)

Property Lists

- Property Lists are Key-Value storage mechanisms
 - If a process needs to store a value for a default, it provides a key for identification and a value for that key
- Values can belong to different Value Classes
 - String
 - Number
 - Boolean
 - Date
 - Array
 - Dictionary
 - Data

Property List Formats

- There are currently 3 Property List file formats:
 - XML
 - ASCII (NeXT-style)
 - Binary
- Property Lists are stored with the file extension `.plist`
- The Property list infrastructure can read/write all 3 formats
 - Humans can read/write the first 2 formats
 - Binary format human-unreadable, but is parsed MUCH faster by the OS
 - faster booting
 - faster application launching

Property List Formats: XML

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE plist PUBLIC "-//Apple Computer//DTD PLIST 1.0//EN" "http://www.apple.com/
DTDs/PropertyList-1.0.dtd">
<plist version="1.0">
<dict>
  <key>AppendAMPM</key>
  <true/>
  <key>ClockDigital</key>
  <integer>1</integer>
  <key>ClockEnabled</key>
  <true/>
  <key>ClockLocation</key>
  <integer>0</integer>
  <key>DisplaySeconds</key>
  <false/>
  <key>FlashSeparators</key>
  <false/>
  <key>LastSavedGlobalTimeString</key>
  <string>h:mm:ss a</string>
  <key>PreferencesVersion</key>
  <integer>2</integer>
  <key>ShowDay</key>
  <true/>
  <key>Transparency</key>
  <real>0.80000001192092896</real>
  <key>Use24HourClock</key>
  <false/>
</dict>
</plist>
```

Property List Formats: ASCII/NeXT

```
{  
  AppendAMPM = 1;  
  ClockDigital = 1;  
  ClockEnabled = 1;  
  ClockLocation = 0;  
  DisplaySeconds = 0;  
  FlashSeparators = 0;  
  LastSavedGlobalTimeString = "h:mm:ss a";  
  PreferencesVersion = 2;  
  ShowDay = 1;  
  Transparency = 0.800000011920929;  
  Use24HourClock = 0;  
}
```

Property List Formats: Binary

bplist00?

Yh:mm:ss a#? 辰 FN[fs?????????????

Editing Property Lists

- Text Editor/command-line text editors
 - Doesn't work with Binary (unless converted, which we will soon see how to do)
- Property List Editor
 - Located in /Developer/Applications/Utilities
 - NOT installed by default on OS X or OS X Server
 - Really should be...
 - Until it is, good thing we're here now!

Converting from one plist format to another

- “Save To” option of Property List Editor
- command-line `plutil` tool

Property Lists: Summary

- YOU are now empowered to edit property list files directly
 - double-edged sword: you can also SCREW UP a process' configuration, making your process (or even entire machine) unusable
 - Comes in handy for troubleshooting, especially in single user mode
- Any Questions?

Property Lists Locations

- OS X has a standard hierarchical resource search policy (for Fonts, etc.):
 - ~/Library/*
 - /Library/*
 - /Network/Library/* (if it exists)
 - /System/Library/*
- Property Lists are **NOT** searched hierarchically and can be stored **ANYWHERE**, including:
 - /etc/*
 - Application Bundles
 - Preferences (but where?)

Preferences: Defaults Infrastructure

- OS X has a mechanism called Defaults that is a “portal” into the Preferences plist system for processes
 - It does NOT incorporate EVERY plist on the system (phew!), only the ones dedicated to preferences
 - Processes themselves don’t need to understand how to read/write or find plist files, they use the Defaults infrastructure
 - Your scripts can leverage this infrastructure and be able to save their own preferences!

Defaults Infrastructure

- Location of Preference files:
 - ~/Library/Preferences
 - /Library/Preferences
 - /var/root/Library/Preferences
- Most files in these folders are in plist format
- Note that some files in */Preferences are NOT plist format
 - These will not be accessible through the Defaults system, but are read directly by the process that owns that preference

Defaults Domains

- Preferences in the Defaults system are organized by domain (and, optionally, host)
 - Typically correspond to individual applications/processes
- Nomenclature for these domains typically (not always) follows Java reverse-FQDN syntax **WITHOUT** the .plist extension
 - Prevents namespace collisions
 - Examples:
 - com.apple.menubar.clock
 - loginwindow

Accessing Defaults

- Defaults are accessed using the CLI tool `defaults`
 - When only a Domain is specified, `defaults` searches `~/Library/Preferences` for a plist file matching the Domain argument with `.plist` appended
 - Example:

```
defaults read com.apple.menubar.clock
```
 - Note that output from `defaults` is in ASCII/NeXT format, independent of the plist format itself (Binary, XML, or ASCII/NeXT)
 - VERY useful in automation and scripting!

Reading/Writing Values for Specific Keys

- A specific key can be read using the same defaults tool
 - Example:

```
defaults read com.apple.menubar.clock  
ClockEnabled
```
- A key's value can be modified:
 - Example:

```
defaults write com.apple.menubar.clock  
ClockEnabled 0
```

Other Defaults Domains

- `NSGlobalDomain`
 - Used for default shared key-value combos, not process or domain-specific
 - Can use `-g` instead of specifying `NSGlobalDomain`
 - Example:

```
defaults read NSGlobalDomain  
AppleMiniaturizeOnDoubleClick  
defaults read -g  
AppleMiniaturizeOnDoubleClick
```

Other Defaults Domains (cont.)

- A full path to a .plist file (minus the .plist extension) can be specified as a domain
 - Example:

```
defaults read /Library/Preferences/  
.GlobalPreferences
```
- Take a look at the Domains available in each of the Preference file locations:
 - ~/Library/Preferences
 - /Library/Preferences
 - /var/root/Library/Preferences

Specifying a Host with Defaults

- The `ByHost` folder seen in some of the previous Preference locations stores host-specific information
 - Useful for processes that utilize more than one host, and want to have host-specific preferences
- You may specify a hostname as either a MAC (IP) address or `-currentHost`

- Examples:

```
defaults -currentHost read  
com.apple.networkConnect
```

```
defaults -host 000a95a92943 read
```

Where is the .plist for NSGlobalDomain?

```
~/Library/Preferences/  
ByHost.GlobalPreferences.MacAddress  
.plist
```

- This is an FYI, since you really should be using defaults to edit the global data (it's MUCH easier!)

Defaults (Summary)

- Preferences are managed through the Defaults infrastructure, and stored in plist files in specific Domains
- You can leverage the `defaults` command to read/write pre-existing domains
- You can also use `defaults` to create/read/write/delete preferences on-the-fly
 - Even scripts you write or leverage can have saved preferences--sure comes in handy for automating workflows!
- Any questions?

launchd

- The launchd daemon process is new to OS X Tiger, and replaces MANY previous processes and methods that controlled the launch of processes:
 - rc files
 - init
 - inetd/xinetd
 - SystemStarter
- launchd is controlled via Property Lists and commands that load/unload those plists

launchd.plist

- The plist files that control launchd are stored in one of the following places:
 - ~/Library/Launch{Agents, Daemons}
 - /Library/Launch{Agents, Daemons}
 - /System/Library/Launch{Agents, Daemons}
- Like any plist, the files consists of a set of Keys-Values that define properties
 - You set the right keys to the right values, and YOU become the boss!

launchd.plist

Mandatory Keys

- Label
 - A unique identifier for this process
- Program
 - Absolute path to the executable file which launches the process
 - optional if ProgramArguments specifies launch path
- ProgramArguments
 - An array of arguments for the process

launchd.plist

Some Optional Keys

- `UserName`
 - The username under which the process should run
- `RootDirectory`
 - A directory that will be the root directory for the process (using `chroot`)
- `WatchPaths`
 - A list of paths that, when modified, will cause the process to launch (if not already launched)
- `StartInterval`
 - An interval in seconds specifying how often the process should be started
- `StandardCalendarInterval`
 - A specification of a repeated calendar interval

launchctl

- Used to load/unload launchd.plist files into the launchd system
- Must be run as root (usually with `sudo`)
- Example:

```
sudo launchctl load ~/Library/  
LaunchAgents/com.apple.TextEdit.plist
```

```
sudo launchctl unload ~/Library/  
LaunchAgents/com.apple.TextEdit.plist
```

Walk-Through: TextEdit

- We are going to create a simple plist file for TextEdit to ensure that it is always running

launchd (Summary)

- We have only scratched the surface of launchd here
 - Please consult online documentation and the man pages for launchd, launchd.plist, launchctl, etc.
- Any Questions?

AppleScript

- One of the (if not THE) easiest scripting languages to learn
- Syntax is flexible, and punctuation is not as necessary (semi-colons and braces and back ticks OH MY!)
- AppleScript can easily call Unix scripts or programs (this bullet is what your English teacher would call “foreshadowing”)
- Unix scripts and programs can easily call AppleScripts through the Open Scripting Architecture (OSA)

Apple Events

- Apple Events are commands that are sent to an application
- MANY applications AppleScript-able through Apple Events
- Apple Events are defined for each Apple Event-compatible application
 - Standard Suite
 - Application-specific
- Use Script Editor to see what Apple Events an application supports

AppleScript Example

```
tell application "Finder"  
  set finderWins to (every Finder window)  
  repeat with w in finderWins  
    set finderWindowName to name of w  
    display dialog finderWindowName  
  end repeat  
end tell
```

ScriptEditor Record Mode

- Will record your actions and create AppleScript commands from them!
- Great for creating a template script that you can modify/addend
- Limited by what events the application provides for recording
 - It often seems like the ONETHING you need is missing

Bringing Executables into AppleScript

- So how can we incorporate programs that don't respond to Apple Events into our flow?
- How can we make applications that only run in the Terminal (referred to as Tools by Apple, rather than Applications) be double-clickable for neophyte, Terminal-phobic users?

AppleScript Example

```
property command : "ls  "

set x to display dialog "Enter path to
show listing" default answer "" buttons
{"Cancel", "Show Me!"} default button
"Show Me!"
if button returned of x is "Show Me!" then
    try
        set filePath to text returned of x
        set output to do shell script command
        & filePath
        display dialog output
    end try
end if
```

Running AppleScripts from Unix scripts

- Use `osascript` command
- OSA stands for Open Scripting Architecture
 - There is an OSA-compatible implementation of JavaScript
<http://www.latenightsw.com/freeware/JavaScriptOSA/>
- So why is this cool...?
 - Answer: UNIX scripts can now ALSO access AppleEvent-supported applications
 - Quicktime compression
 - Adobe CS
 - etc.

AppleScript Droplets

- AppleScripts can be written as Droplets, which allow things to be “dropped” onto them
- Dialogs can then be optional, and the script will operate on all files/folders dropped onto it
- Great for workflow automation

AppleScript Studio: Adding a GUI

- We have seen how to make AppleScripts communicate with pre-existing programs
- Wouldn't it be COOL if we could use Apple Developer Tools to put a fancy GUI in front of command-line tools?
- We can leverage the same Interface Builder that is used to develop Cocoa apps for AppleScripts

AppleScript & A.S. Studio Summary

- Intuitive, syntax-friendly scripting language
- Part of DNA of OS X
 - Apple Events
 - Droplets
- AppleScript Studio bring power of full-powered GUI to your scripts without ANY programming (just connect-the-dots)
- Any Questions?

Automator

- Brand-new to Tiger
- Connects applications together in a workflow without ANY scripting/programming
 - Notice the icon, and how it is “pipe-ing” :-)

Automator

- Automator Actions not directly correlated with Apple Events
 - Automator actions are added by “real” programmers to the applications so that other can use them (as are Apple Events, but in a different way)
 - Automator Actions can be written as Apple Scripts
 - Only a small subset of Apple Events have made it to Automator Actions right now (but this will change)
 - In Automator’s current defense, there are some things in Automator that would be a pain to do in AppleScript

Automator (summary)

- Automator is destined to be a VERY important part of OS X
 - Still in embryonic/newborn stage right now
 - VERY good support infrastructure exists already in the community
 - If you find Automator limiting right now, be patient, this is going to be HUGE
- Any Questions?

Synopsis

- Even non-programmers have the power to harness developer tools
- You can use Property List Editor to
 - Edit process' properties
 - Control the launching of applications with `launchd`
- You can use the Preference Defaults system for troubleshooting and control
- You can create scripts/programs (or get them off the Internet!) and add fancy GUIs to them with AppleScript Studio
- You can automate workflows with Automator

Resources

- Install the Developer tools!
 - Tiger DVD
 - Download: <http://developer.apple.com/>
 - Get ADC membership (Online membership is free)
- Property List Editor and the Defaults Preferences System
 - man pages
- launchd
